## **ACKNOWLEDGEMENTS**

My sincere gratitude is sent to my supervisor Dr. E C Webb who played an important role in the preparation and carrying out of this research project. Without Dr. E C Webb the programme of study would have ended quite prematurely and the study would therefore have been a non-starter.

Special thanks also go to Prof. A J Ngomuo for research funding and guidance. He also provided his expertise on the topic that I was working on.

My special recognition goes to farmers around Serowe Village who allowed me to use their cattle during my study period. I would like to thank all temporary workers who helped me during the tick collection procedures and application of Neem seed extract on the test animals.

I would like to express my gratitude to my typist and my wife Pamela who worked overtime to finish this work. Finally I would like to thank my friends and family for their support.

## Abstract

Matayo David (Dr)

### **TICK CONTROL IN TSWANA, BRAHMAN AND SIMMENTAL BY MEANS OF NEEM SEED EXTRACTS**

Supervisor: Dr. EC Webb

A total of 114 animals (57 bulls and 57 cows) of Tswana, Brahman and Simmental cattle were used for the three trials (Trial 1, 2 and 3). All animals were 15 months old and above. In the first trial a total of 9 animals were spread on the perennial area, ear, dewlap, udder, scrotum, and sternal area with either 5% (W/V) water extract of Neem Seed Kernel NSK at a rate of 5g/kg body weight, some 9 animals were sprayed with tap water (control group).

During the 2<sup>nd</sup> trial a total of 30 animals were spread with 2% (W/V) ethanolic neem seed extract (NSKE) 2% (W/V) ethanol extract of neem seed oil at a rate of 5g/Kg body weight some 30 animals were similarly sprayed with tap water as control group. During the 1<sup>st</sup> and the 2<sup>nd</sup> trial an experimental and control animals were kept in separate partitions of the shelter, but grazed together in the area which was heavily infested with adults and immature stages of ticks. In the 3<sup>rd</sup> trial a total of 36 animals were artificially infested with tick, 18 cattle were spread with 3% (W/V) ethanolic Neem Seed Kernel (NSKE) at the rate of 5g/kg body weight. Another 18 animals were spread with tap water as control group, there was no contact between animals although were kept in the same environment. The tick index of each animal for all three trials was determined weekly for 14 months consecutively.

Results showed that mean tick population densities were significantly lower in the experimental than control animals. Indigenous Tswana cattle harboured significantly fewer ticks during periods of peak tick abundance than either Brahman or Simmental cattle. Fewer

abscesses due to tick bites were observed in Tswana than the other two breeds, and a large percentage of Tswana cattle showed a high tick resistance. The results suggest a high degree of natural immunity in indigenous Tswana cattle.

It was concluded that NSKE extract was potentially useful in controlling ticks on livestock. Further research is required to study the active ingredients in NSKE as well as the pharmacological action on ticks. It is recommended that NSKE should be considered for inclusion in the management programmes to control ectoparasites on livestock.
