Abstract: A concatenated dataset of LSU, SSU, ITS and *tef1* DNA sequence data was analysed to investigate the taxonomic position and phylogenetic relationships of the genus *Camarosporium* in *Pleosporineae* (*Dothideomycetes*). Newly generated sequences from *camarosporium*-like taxa collected from Europe (Italy) and Russia form a well-supported monophyletic clade within *Pleosporineae*. A new genus *Camarosporidiella* and a new family *Camarosporidiellaceae* are established to accommodate these taxa. Four new species, *Neocamarosporium korfii*, *N. lamiacearum*, *N. salicorniicola* and *N. salsolae*, constitute a strongly supported clade with several known taxa for which the new family, *Neocamarosporiaceae*, is introduced. The genus *Staurospheeria* based on *S. lycii* is resurrected and epitypified, and shown to accommodate the recently introduced genus *Hazslinszkyomyces* in *Coniothyriaceae* with significant statistical support. *Camarosporium quaternatum*, the type species of *Camarosporium* and *Camarosporomyces flavigena* cluster together in a monophyletic clade with significant statistical support and sister to the *Leptosphaeriaceae*. To better resolve interfamilial/intergeneric level relationships and improve taxonomic understanding within *Pleosporineae*, we validate *Camarosporiaceae* to accommodate *Camarosporium* and *Camarosporomyces*. The latter taxa along with other species are described in this study.

Key words: Multigene phylogeny, Muriformly septate, Pleomorphism, *Pleosporales*, Taxonomy.

Taxonomic novelties: **New families:** *Camarosporiaceae* Wanas., K.D. Hyde & Crous, *Camarosporidiellaceae* Wanas., Wijyaw., Crous & K.D. Hyde, *Neocamarosporiaceae* Wanas., Wijyaw., Crous & K.D. Hyde; **New genus:** *Camarosporidiella* Wanas., Wijyaw. & K.D. Hyde; **New species:** *Camarosporidiella elaeagnicola* Wanas., Bulgakov & K.D. Hyde, *Ca. eufemiana* Wanas., Camporesi & K.D. Hyde, *Ca. halimodendri* Wanas., Bulgakov & K.D. Hyde, *Ca. italic* Wanas., Camporesi & K.D. Hyde, *Ca. mackenziei* Wanas., Bulgakov & K.D. Hyde, *Ca. melnikii* Wanas., Bulgakov & K.D. INTRODUCTION

Morphological characteristics, cultural studies and host-fungal association have been considered as important aspects in the traditional taxonomy of coelomycetous fungi (Sutton 1980, Sivanesan 1984, Nag Raj 1993, Jeewon et al. 2002, 2003b, 2004, Wijayawardene et al. 2016). However, morphological plasticity of several coelomycetous genera led to poor generic

and species delimitation, often resulting in incorrect taxonomic placement (Jeewon et al. 2003a, Shenoy et al. 2007, Wijayawardene et al. 2016). Proposing new genera (e.g. *Vermisporium*/*Seimatosporium*, fide Barber et al. 2011) and linking asexual genera with more than one sexual genus (e.g. *Phoma* and *Camarosporium*, fide Crous & Groenewald 2017) have resulted in taxonomic controversies among taxonomists and plant-pathologists (Wijayawardene et al. 2012a, b, Hyde et al.

2013, Crous et al. 2015a). DNA-based sequence analyses have so far provided reliable evidence for more precise generic boundaries (e.g. *Pestalotiopsis* *fide* Jeewon et al. 2003b, 2004, *Maharachchikumbura* et al. 2012, 2014a, b, *Phoma* *fide* de Gruyter et al. 2009, 2012, Chen et al. 2015, *Camarosporium* *fide* Crous et al. 2013, Wijayawardene et al. 2014b, 2015, 2016, *Coniothyrium* *fide* Verkley et al. 2004, 2014, Wijayawardene et al. 2016) and resolution of species complexes (e.g. *Diplodia* *fide* Phillips et al. 2008, *Colletotrichum* *fide* Damm et al. 2012, 2014).

The genus *Camarosporium* was introduced by Schulzer (1870) with *Cm. quaternatum* as the type species, and it is one of the largest coelomycetous genera, comprising over 500 epithets in Index Fungorum (2017). Several *Camarosporium* species have been reported as important plant pathogens with a worldwide distribution. *Camarosporium pistaciae* is known as a common pathogen responsible for blight of the shoots and panicles in pistachio production in Greece (Assimakopoulou & Elena 2010). Smith et al. (1988) listed *Camarosporium dalmaticum*, *Cm. flaccidum*, *Cm. pistaciae*, and *Cm. strobilinum* as plant pathogens in Europe. *Camarosporium* species are reported as causing damage in the cut-flower industry in the USA. (Taylor et al. 2001). *Camarosporium* species are also reported as common pathogens of deciduous trees in Europe and *Cm. pini* induces severe infection that can result in significant growth reduction to pine plantations (Ivanová & Bernadovičová 2010).

Sutton (1980) pointed out the heterogeneity of the genus, citing *Camarosporium propinquum* as an example. Sutton's (1980) prediction was confirmed by Wijayawardene et al. (2014c), who reported that *Cm. propinquum* should be accommodated in *Didymosphaeriaceae*. *Camarosporium* has been linked to *Cucurbitaria* (Kirk et al. 2008, Wijayawardene et al. 2012b, Doilom et al. 2013), *Leptosphaeriaceae* (Schoch et al. 2009) and *Botryosphaerales* (Kirk et al. 2008, Liu et al. 2012, Wijayawardene et al. 2012b), although Crous et al. (2006) reported that *Cm. quaternatum* (based on CBS 134.97 culture, now described as *Libertasomyces querqus*; Crous & Groenewald 2017) does not belong to the *Botryosphaerales*. Further evidence was provided that *camarosporium*-like taxa are polyphyletic within *Pleosporales* (Crous et al. 2014a, b, Wanasinghe et al. 2014a, Wijayawardene et al. 2014a, c, 2016, Crous & Groenewald 2017), leading to more taxonomic confusion of *Camarosporium* and *camarosporium*-like taxa. In a recent study, Crous & Groenewald (2017) designated an epitype for *Cm. quaternatum* and treated *Camarosporium* s. str. in *Coniothyriaceae*, and reported this complex to have phoma-like synasexual morphs, and pleospora-like sexual morphs. To date there is DNA sequence data for only a small number of species, and the validity of taxonomic concepts and other species remains uncertain. Therefore, it has been necessary to recollect these taxa from type localities, isolate them in axenic culture, and analyse their DNA sequence data to better understand their morpho- and phylotaxyonomy. Given the considerable taxonomic confusion among *Camarosporium* and its allies and its familial placement, this study was undertaken to answer the following questions: (i) Do *camarosporium*-like taxa represent a natural group?; (ii) What are the allied sexual and synasexual morphs of *camarosporium*-like taxa?; (iii) Where does *Camarosporium quaternatum* position itself within the *Pleosporineae*?

MATERIALS AND METHODS

Specimens and isolates

Fresh *camarosporium*-like specimens were collected in Europe (Russia and Italy) and Asia (Thailand and Uzbekistan) from various host plants. Uzbekistan specimens were loaned from Tashkent Mycological Herbarium (TASM), Tashkent. The specimens were examined following the methods described in Wanasinghe et al. (2014a). Axenic strains were established from single spores as described in Chomnunti et al. (2014), with a modification of the incubation temperature at 16 °C overnight in the dark. Germinated ascospores and conidia were observed with a Motic SMZ 168 Stereo Zoom microscope and transferred to potato dextrose agar (PDA; 39 g/L distilled water, Difco potato dextrose) for extraction of DNA, determination of growth rates and observation of cultural characteristics. The specimens are deposited at Mae Fah Luang University (MFLU) Herbarium, Chiang Rai, Thailand and the New Zealand Fungal Herbarium (PDD). Living cultures are deposited at the Culture Collection of Mae Fah Luang University (MFLUCC) and the Westerdijk Fungal Biodiversity Institute in Utrecht, the Netherlands (CBS)

Morphological classification

Digital images of the fruiting structures were captured with a Canon 450D digital camera fitted to a Nikon ECLIPSE 80i compound microscope. Squash mount preparations were prepared to determine micro-morphology, and free hand sections of sporocarps made to observe the shapes of ascomata/conidiomata and peridium structures. Measurements of morphological structures were taken from the widest part of each structure. Whenever possible, more than 30 measurements were made. The lengths and widths were measured using the Tarosoft (R) Image Frame Work program and images used for figures processed with Adobe Photoshop CS3 Extended v. 10.0 (Adobe®, San Jose, CA). Three sets of duplicate cultures of each isolate were measured to determine colony characteristics on PDA at 16 °C in the dark. Colony size was determined, and colour rated according to the colour charts of Rayner (1970) after 3 wk of incubation.

DNA extraction, PCR and sequencing

Isolates were grown on PDA for 3–4 wk at 16 °C and total genomic DNA was extracted from 50 to 100 mg of mycelium scraped from the edges of the growing cultures (Wu et al. 2001). Mycelium was ground to a fine powder in liquid nitrogen and DNA was extracted using the Biospin Fungus Genomic DNA Extraction Kit, BSC14S1 (BioFlux, P.R. China) following the instructions of the manufacturer. When fungi failed to germinate and grow in culture, DNA was extracted directly from ascomata using a DNA extraction kit (E.Z.N.A.® Forensic DNA kit, D3591-01, Omega Bio-Tek) following Telle & Thines (2008). DNA were stored at 4 °C for use in regular work and duplicated at -20 °C for long term storage. DNA sequence data was obtained from the partial sequences of four loci: the internal transcribed spacers (ITS1-5.8S nrDNA-ITS2, ITS), small subunit nrDNA (18S, SSU), large subunit nrDNA (28S, LSU) and translation elongation factor 1-alpha gene (*tef1*). Nuclear ITS regions were amplified using the primers ITS5 and ITS4 (White et al. 1990). The LSU was amplified using the primers LROR (Rehner &

Samuels 1994) and LR5 (Vilgalys & Hester 1990), the SSU using the primers NS1 and NS4 (White *et al.* 1990), and *tef1* using primers EF1-983F and EF1-2218R (Rehner & Buckley 2005). The polymerase chain reaction (PCR) was carried out with a final volume of 25 µL under the following protocol: 12.5 µL of 2 × Power Taq PCR MasterMix (a premix and ready to use solution, including 0.1 Units/µL Taq DNA Polymerase, 500 µM dNTP Mixture each (dATP, dCTP, dGTP, dTTP), 20 mM Tris-HCl pH 8.3, 100 mM KCl, 3 mM MgCl₂, stabilizer and enhancer), 1 µL of each primer (10 µM), 1 µL genomic DNA extract and 9.5 µL deionised water. The reaction was then allowed to run for 35 cycles. The PCR profile was as follows: initial denaturation 95 °C for 5 min, 35 cycles of denaturation at 95 °C for 90 s, annealing for 90 s, elongation at 72 °C for 1 min, and final extension at 72 °C for 10 min. The annealing temperature was 55 °C for ITS, LSU, *tef1* and 48 °C for SSU. The amplified PCR fragments were sequenced by BGI, Ltd., Shenzhen, P.R. China. Sequences were deposited in GenBank (Tables 1 and 2).

Sequence alignment and phylogenetic analyses

Sequences generated from different primers of the four genes were analysed with other sequences retrieved from GenBank. Sequences with high similarity indices were determined from a BLAST search to find the closest matches with taxa in *Pleosporineae*, and from recently published data (Liu *et al.* 2015, Grum-Grzhimaylo *et al.* 2016, Crous & Groenewald 2017, Tibpromma *et al.* 2017). The sequences were aligned in MAFFT v. 7 with the web server (<http://mafft.cbrc.jp/alignment/server>), using iterative refinements as E-INS-i method for ITS & *tef1*, and as G-INS-i method for LSU and SSU (Katoh & Standley 2013). The alignment was edited where necessary with BioEdit v. 7.0.5.2 (Hall 1999). The alignment properties for the individual genes are shown in the Table 3. The final alignment and tree were deposited in TreeBASE, submission ID: 21397 (<http://www.treebase.org/>).

The final alignment (combined LSU, SSU, *tef1* and ITS loci) included 212 strains, (representing 16 selected families within the *Pleosporineae*), the new taxa proposed in this study, and *Cyclothyriella rubronotata* (CBS 141486 & CBS 121892) as the out-group taxon. Phylogenetic analyses of both individual and combined aligned data were based on Maximum Likelihood (ML), Maximum Parsimony (MP) and Bayesian analyses. The sequence alignments were converted to NEXUS file format (.nex) for maximum parsimony and Bayesian analyses using ClustalX2 v. 1.83 (Thompson *et al.* 1997). The NEXUS file was prepared for MrModeltest v. 2.2 after deleting the symbols =“ABCDEFGHI-KLMNOPQRSTUVWXYZ” (Nylander 2004) in PAUP (Phylogenetic Analysis Using Parsimony) v. 4.0b10 (Swofford 2003). For the Randomized Accelerated Maximum Likelihood (RAxML) analysis, sequence alignments were converted to PHYLIP file format (.phy) using ALTER (alignment transformation environment: <http://sing.ei.uvigo.es/ALTER/>; 2017).

The MP bootstrap analysis was performed with PAUP, with 1000 bootstrap replicates using 10 rounds of heuristic search replicates with random addition of sequences and subsequent TBR branch swapping (MULTREES option in effect, steepest descent option not in effect) during each bootstrap replicate, with each replicate limited to 1 M rearrangements. All characters were unordered and given equal weight; gaps were treated as missing data; the COLLAPSE command was set to minbrlen. Descriptive tree statistics for parsimony were calculated for trees generated under different optimality criteria: Tree Length (TL), Consistency

Index (CI), Retention Index (RI), Relative Consistency Index (RC) and Homoplasy Index (HI). The Kishino-Hasegawa tests (Kishino & Hasegawa 1989) were performed to determine whether trees were significantly different. Other details are outlined in Jeewon *et al.* (2003b) and Promputtha *et al.* (2007).

The evolutionary models for Bayesian analysis and ML were selected independently for each locus using MrModeltest v. 2.3 (Nylander 2004) under the Akaike Information Criterion (AIC) implemented in PAUP v. 4.0b10. The GTR + I + G model was selected as the best-fit model for each locus in both Bayesian and ML analyses.

The Bayesian analysis was performed in MrBayes v. 3.1.2 (Huelsenbeck & Ronqvist 2001) to evaluate Posterior probabilities (PP) (Rannala & Yang 1996, Zhaxybayeva & Gogarten 2002) by Markov Chain Monte Carlo sampling (BMCMB). Six simultaneous Markov chains were run for 5 M generations and trees were sampled every 500th generation. The distribution of log-likelihood scores was examined to determine the stationary phase for each search and to decide if extra runs were required to achieve convergence, using the program Tracer v. 1.5 (Rambaut & Drummond 2007). All sampled topologies beneath the asymptote (10 %) were discarded as part of a burn-in procedure; the remaining trees were used for calculating PP in the majority rule consensus tree.

The ML trees were generated using the RAxML-HPC2 on XSEDE (v. 8.2.8) (Stamatakis *et al.* 2008, Stamatakis 2014) in the CIPRES Science Gateway platform (Miller *et al.* 2010) using a GTR + I + G model of evolution. Phylogenograms were visualised with FigTree v. 1.4.0 (Rambaut 2012) and annotated in Microsoft PowerPoint (2007) or Adobe Illustrator® CS5 (v. 15.0.0, Adobe®, San Jose, CA).

RESULTS

Phylogenetic analyses

Topologies of trees (ML, MP and PP) for each gene dataset were compared and the overall tree topology was congruent to those obtained from the combined dataset.

The RAxML analysis of the combined dataset yielded a best scoring tree (Fig. 1) with a final ML optimisation likelihood value of -24419.107973. The matrix had 1 273 distinct alignment patterns, with 24.87 % of undetermined characters or gaps. Parameters for the GTR + I + G model of the combined LSU, SSU, *tef1* and ITS were as follows: Estimated base frequencies; A = 0.24346, C = 0.239263, G = 0.26821, T = 0.249067; substitution rates AC = 1.464074, AG = 3.479937, AT = 2.089279, CG = 0.715575, CT = 7.524749, GT = 1.000; proportion of invariable sites I = 0.630738; gamma distribution shape parameter α = 0.492847. The maximum parsimonious dataset consisted of 3 461 characters, of which 2 583 were constant, 745 parsimony-informative and 133 parsimony-uninformative. The parsimony analysis of the data matrix resulted in the maximum of 1 000 equally most parsimonious trees with a length of 3 928 steps (CI = 0.341, RI = 0.793, RC = 0.27, HI = 0.659) in the first tree. The Bayesian analysis resulted in 10 000 trees after 5 M generations. The first 1 000 trees, representing the burn-in phase of the analyses, were discarded, while the remaining 9 000 trees were used for calculating posterior probabilities in the majority rule consensus tree.

Simmons; IBRC: Iranian Biological Resources Center, Academic Center for Education Culture and Research (ACECR), Tehran, Iran; JK: J. Kohlmeyer; MFLUCC/MFLU: Mae Fah Luang University Culture Collection, Chiang Rai, Thailand; NBRC: NITE Biological Resource Center, Department of Biotechnology, National Institute of Technology and Evaluation, Kisarazu, Chiba, Japan. *Strain designation from GenBank.

² ITS: Internal transcribed spacers; LSU: partial 28S nrDNA; SSU: partial 18S nrDNA; tef1: translation elongation factor 1-alpha gene.

Newly generated sequences from 75 isolates of camarosporium-like taxa grouped with *Camarosporium aborescentis*, *Cm. arezzoensis*, *Cm. aureum*, *Cm. caraganicola*, *Cm. clematidis*, *Cm. elaeagnellum*, *Cm. elongata*, *Cm. laburnicola*, *Cm. moricola*, *Cm. robinicola*, *Cm. spartii*, *Cm. uniseriatum* and *Cucurbitaria elongata* (*fide* Wijayawardene *et al.* 2014a, b, 2016, Tibpromma *et al.* 2015, 2017, Thambugala *et al.* 2016, Crous & Groenewald 2017). These taxa formed an isolated, well-supported clade (97 % ML, 97 % MP and 1.00 PP, Clade A, Fig. 1) within *Pleosporineae* which we formally introduce as *Camarosporidiellaceae*.

Six newly generated sequences, *Staurophaeria lycii* (MFLUCC 17-0210, MFLUCC 17-0211, MFLUCC 17-0720 and MFLUCC 17-0721), *S. rhamnicola* (MFLUCC 17-0813 and MFLUCC 17-0814) grouped with *Hazslinszkyomyces lycii* (CPC 31014 and CPC 30998), the type species of *Hazslinszkyomyces*, *H. aptrootii* (CBS 483.95) and *H. aloes* (CPC 21572). These taxa form a monophyletic clade (Clade B) in *Coniothyriaceae* with significant statistical support (92 % ML, 83 % MP and 1.00 PP, Fig. 1) and hereby being referred to as the genus *Staurophaeria*.

Camarosporium quaternatum and *Camarosporomyces flavi-*genus always grouped together in a separate clade with high statistical support (86 % ML, 70 % MP and 1.00 PP, Clade C, Fig. 1). In different analyses, the placement of this clade is unstable and in this concatenated analysis, these taxa are basal to the *Leptosphaeriaceae*. We herein validate *Camarosporiaceae* to accommodate *Camarosporium* and *Camarosporomyces*.

Neocamarosporium korfii (MFLUCC 17-0745), *N. lamiaeum* (MFLUCC 17-560 and MFLUCC 17-0750), *N. salicornicola* (MFLUCC 15-0957) and *N. salsolae* (MFLUCC 17-0826 and MFLUCC 17-0827) grouped with *Coniothyrium obiones* (CBS 453.68), *Dimorphosporicola tragani* (CBS 570.85), *Neocamarosporium betae* (CBS 109410 and CBS 523.66), *N. calvescens* (CBS 246.79), *N. chenopodii* (CBS 344.78), *N.*

chersiniae (CPC 27298), *N. chichastianum* (CBS 137502), *N. goegapense* (CPC 23676), *N. obiones* (CBS 432.77) and *Neocamarosporium* sp. (IBRC M 30134, IBRC M 30264, IBRC M 30177, IBRC M 30257, IBRC M 30243, IBRC M 30263, M303, M305 and M311) from a distinct clade (Clade D) with high bootstrap values (95 % and 79 % in ML and MP analyses respectively) and high PP value (1.00). Multi-gene phylogenetic analyses herein support the establishment of a new family, *Neocamarosporiaceae* fam. nov. for Clade D (Fig. 1).

Apart from establishing three new families, our multi-gene phylogeny, with relatively good support, this study also clarifies interfamilial relationships. In particular, we note that all the families herein are well supported monophyletic lineages. The *Cucurbitariaceae* was previously considered as a close ally to *Coniothyriaceae* (Hyde *et al.* 2013), *Phaeosphaeriaceae* (Wijayawardene *et al.* 2014a), *Pleosporaceae* (Doilom *et al.* 2013, Wanasinghe *et al.* 2014b), but this study demonstrates a sister relationship to *Neophaeosphaeriaceae*. It is also interesting to note that *Neocamarosporiaceae* shares close affinities to *Pleosporaceae* and *Libertasomycetaceae*. The affinities of *Foliophoma*, which is characterized by eustromatic conidiomata, uni- to multi-loculate with 1–3 ostioles and conidiogenous cells with periclinal thickening or percurrent proliferation at apex (Crous & Groenewald 2017), warrants further investigations as only one species has been described so far. *Phaeosphaeriaceae* and *Shiraiaceae* are closely related while *Didymellaceae* is sister family to *Dothidotthiaceae*. In other analyses (results not shown) the *Microsphaeropsidaceae* (introduced by Chen *et al.* 2015) clusters basal to the *Didymellaceae*. The other families viz. *Acrocalymmacaceae*, *Ascocylindricaceae* and *Halojulaceae*, with relatively few taxa are basal families of the *Pleosporineae*.

Camarosporiaceae Wanas., Wijyaw., K.D. Hyde & Crous, fam. nov. MycoBank MB821938; Facesoffungi number: FoF 03527.

Synonym: *Camarosporiaceae* Locq., Mycol. gén. struct. (Paris): 210 (1984); nom. inval., Art. 39.1 (Melbourne).

Saprobic, endophytic, pathogenic on leaves and wood in terrestrial habitats. **Asexual morph:** *Conidiomata* dimorphic, pycnidial, subcorticolous, single to gregarious, partly caespitose, globose, ostiole central, terete, short papillate. *Conidiomata wall* few-layered, consisting of a *textura globulosa-angularis* with red brown, thick-walled, and smooth cells. *Conidiogenous cells* formed from the inner cells of the pycnidial wall, doliform, hyaline, thin-walled, annellidic. *Conidia* multicelled, muriformly septate, with one longitudinal or diagonal septum per cell and 1–2 per conidium, ellipsoidal, pyroid, clavate, straight to slightly curved, yellowish not brown, basal cell often paler or hyaline, wall golden. **Synasexual morph:** conidiomata separate, pycnidial, immersed to superficial, brown, globose, with 1–2 papillate ostioles, exuding a crystalline conidial mass. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* lining the inner cavity, hyaline, smooth, ampulliform. *Conidia* solitary, hyaline, smooth, subcylindrical, straight, rarely curved, apex obtuse, base truncate. **Sexual morph:** Ascomata gregarious to solitary, immersed to erumpent, globose to subglobose, black, unilocular, ostiolate. *Ostiole* black, papillate. *Peridium* with several cell layers of *textura angularis*, with outer layer brown to reddish brown, inner layer hyaline to sub hyaline. *Asci* stipitate, cylindrical, bitunicate, (2–)4–8-spored. *Ascospores* uniseriate, ellipsoidal, medium brown, mostly with obtuse ends, muriform, 3–8 transverse septa, with 1–2 longitudinal septa, constricted at septa.

Type genus: *Camarosporium* Schulzer.

Notes: To better resolve interfamilial/intergeneric level relationships and improve taxonomic issues within *Pleosporineae*, we validate *Camarosporiaceae* (*Camarosporiaceae* Locq. 1984 was not validly published, Art. 39.1) to accommodate *Camarosporium* and *Camarosporomyces*. [Wijayawardene et al. \(2014b\)](#) also proposed *Camarosporiaceae* to accommodate *Camarosporium* s. str. but it was not formerly introduced.

Camarosporium Schulzer, Verh. K.K. Zool.-Bot. Ges. Wien 17: 717. 1870.

Description and illustration: [Crous & Groenewald \(2017\)](#).

Type species: *Camarosporium quaternatum* (Hazsl.) Schulzer.

Notes: *Camarosporium* morphologically resembles genera such as *Camarographium*, *Camarosporopsis*, *Camarosporula*, *Dichomera*, *Didymelloclaramosporium*, *Hazslinszkyomyces*, *Libertasomyces*, *Magnicamarosporium*, *Melanocamarosporium*, *Melnikia*, *Murilentithecium*, *Neocamarosporium*, *Paracamarosporium*, *Phragmocamarosporium*, *Pseudocamarosporium*, *Pseudohendersonia*, *Suttonomyces* and *Xenocamarosporium* in conidial shape and septation. However, these taxa are phylogenetically distinct and have subtle but specific morphological differences ([Sutton 1980](#), [Butin 1993](#), [Crous et al. 2011, 2013, 2014b, 2015a, b](#), [Wijayawardene et al. 2014a, 2014b, 2014c, 2015, 2016, Tanaka et al. 2015](#), [Tian et al. 2015](#), [Crous & Groenewald 2017](#)).

Camarosporium quaternatum was introduced by [Schulzer \(1870\)](#) as the type species of *Camarosporium*. [Schulzer \(1870\)](#) did not provide any illustrations for *Camarosporium*.

Table 3. Comparison of alignment properties of genes and nucleotide substitution models used in *Pleosporineae* phylogenetic analyses.

quaternatum in his article and mentioned it is completely similar to *Clinterium lycii*, described in Hazslinszky (1865). The micro-fungal collections of F.A. Hazslinszky von Hazslin are preserved in the Hungarian Natural History Museum (BP), but the type of *Cm. quaternatum* has been lost. Therefore, in a recent study Crous & Groenewald (2017) designated the original illustrations as lectotypes, to facilitate epitypification.

Camarosporomyces Crous, IMA Fungus 8: 141. 2017.

Description and illustration: Crous & Groenewald (2017).

Type species: *Camarosporomyces flavigenus* (Constant. & Aa) Crous.

Notes: *Camarosporomyces* was introduced by Crous & Groenewald (2017) to accommodate *Camarosporomyces flavigenus*, a phoma-like fungus which was originally described as *Phoma flavigena*. In our molecular analyses, *Camarosporomyces flavigenus* is basal to other strains of *Camarosporium quaternatum* strains with good statistical support (Clade C, Fig. 1).

Camarosporidiellaceae Wanas., Wijayaw., Crous & K.D. Hyde, fam. nov. MycoBank MB821939; Facesoffungi number: FoF 03528.

Etymology: Referring to the name of the type genus.

Saprobic or **endophytic** or **pathogenic** on leaves and wood (Fig. 2). **Asexual morph:** Coelomycetous. **Conidiomata** pycnidial, immersed to sub-peridermal, globose, dark brown to black, unilocular. **Conidiomata wall** thick-walled, dark brown, composed of cells of *textura angularis*, inner layer with hyaline cells. **Ostiole** single, circular, centrally papillate. **Conidiogenous cells** enteroblastic, annellidic, integrated to discrete, doliform, lageniform or cylindrical, smooth, hyaline, formed from the inner cells of the pycnidial wall. **Conidia** medium brown to dark brown, phragmosporous to muriform, variable in shape, mostly ellipsoidal, curved to straight, truncate at the base, obtuse at the apex, continuous or constricted at the septa. **Sexual morph:** Ascomata gregarious to solitary, immersed to erumpent, globose to

subglobose, black, unilocular, ostiolate. **Ostiole** black, papillate. **Peridium** with several cell layers of *textura angularis*, with outer layer brown to reddish-brown, inner layer hyaline to sub hyaline. **Asci** stipitate, cylindrical, bitunicate, (2–)4–8-spored. **Ascospores** uniseriate, ellipsoidal, medium brown, mostly with obtuse ends, muriform, 3–8 transverse septa, with 1–2 longitudinal septa, constricted at septa.

Type genus: *Camarosporidiella* Wanas., Wijayaw. & K.D. Hyde.

Notes: *Camarosporidiellaceae* forms a highly-supported monophyletic lineage (97 %/97 %/1.00; Fig. 1, clade A) but lacks internal support. Morphological features are not informative for generic distinction within Clade A. The taxa studied here are treated below according to the phylogenetic clades (Subclades A1–A12, Fig. 1) as follows:

Camarosporidiella Wanas., Wijayaw. & K.D. Hyde, gen. nov. MycoBank MB821940; Facesoffungi number: FoF 03529.

Etymology: Resembling the genus *Camarosporium*.

Saprobic or **endophytic** or **pathogenic** on leaves and wood in terrestrial habitats. **Asexual morph:** Conidiomata pycnidial, immersed to sub-peridermal, globose, dark brown to black, unilocular. **Conidiomata wall** thick-walled, dark brown, composed of cells of *textura angularis*, inner layer with hyaline cells. **Ostiole** single, circular, centrally papillate. **Macroconidiogenous cells** enteroblastic, annellidic, integrated, indeterminate, doliform, lageniform or cylindrical, smooth-walled, hyaline, formed from the inner cells of the pycnidial wall. **Macroconidia** medium brown to dark brown, phragmosporous to muriform, variable in shape, mostly ellipsoidal, curved to straight, truncate at base, obtuse at apex, continuous or constricted at the septa. **Microconidiogenous cells** present or absent in cultures, when present; intermingled with macroconidiogenous cells, hyaline, integrated, enteroblastic, percurrent annellidic, ampulliform to subcylindrical. **Microconidia** present or absent, when present; hyaline, round to oblong or ellipsoidal, with small guttules. **Sexual morph:** cucurbitaria-like. **Ascomata** black, superficial to semi-immersed, gregarious, confluent, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, black,

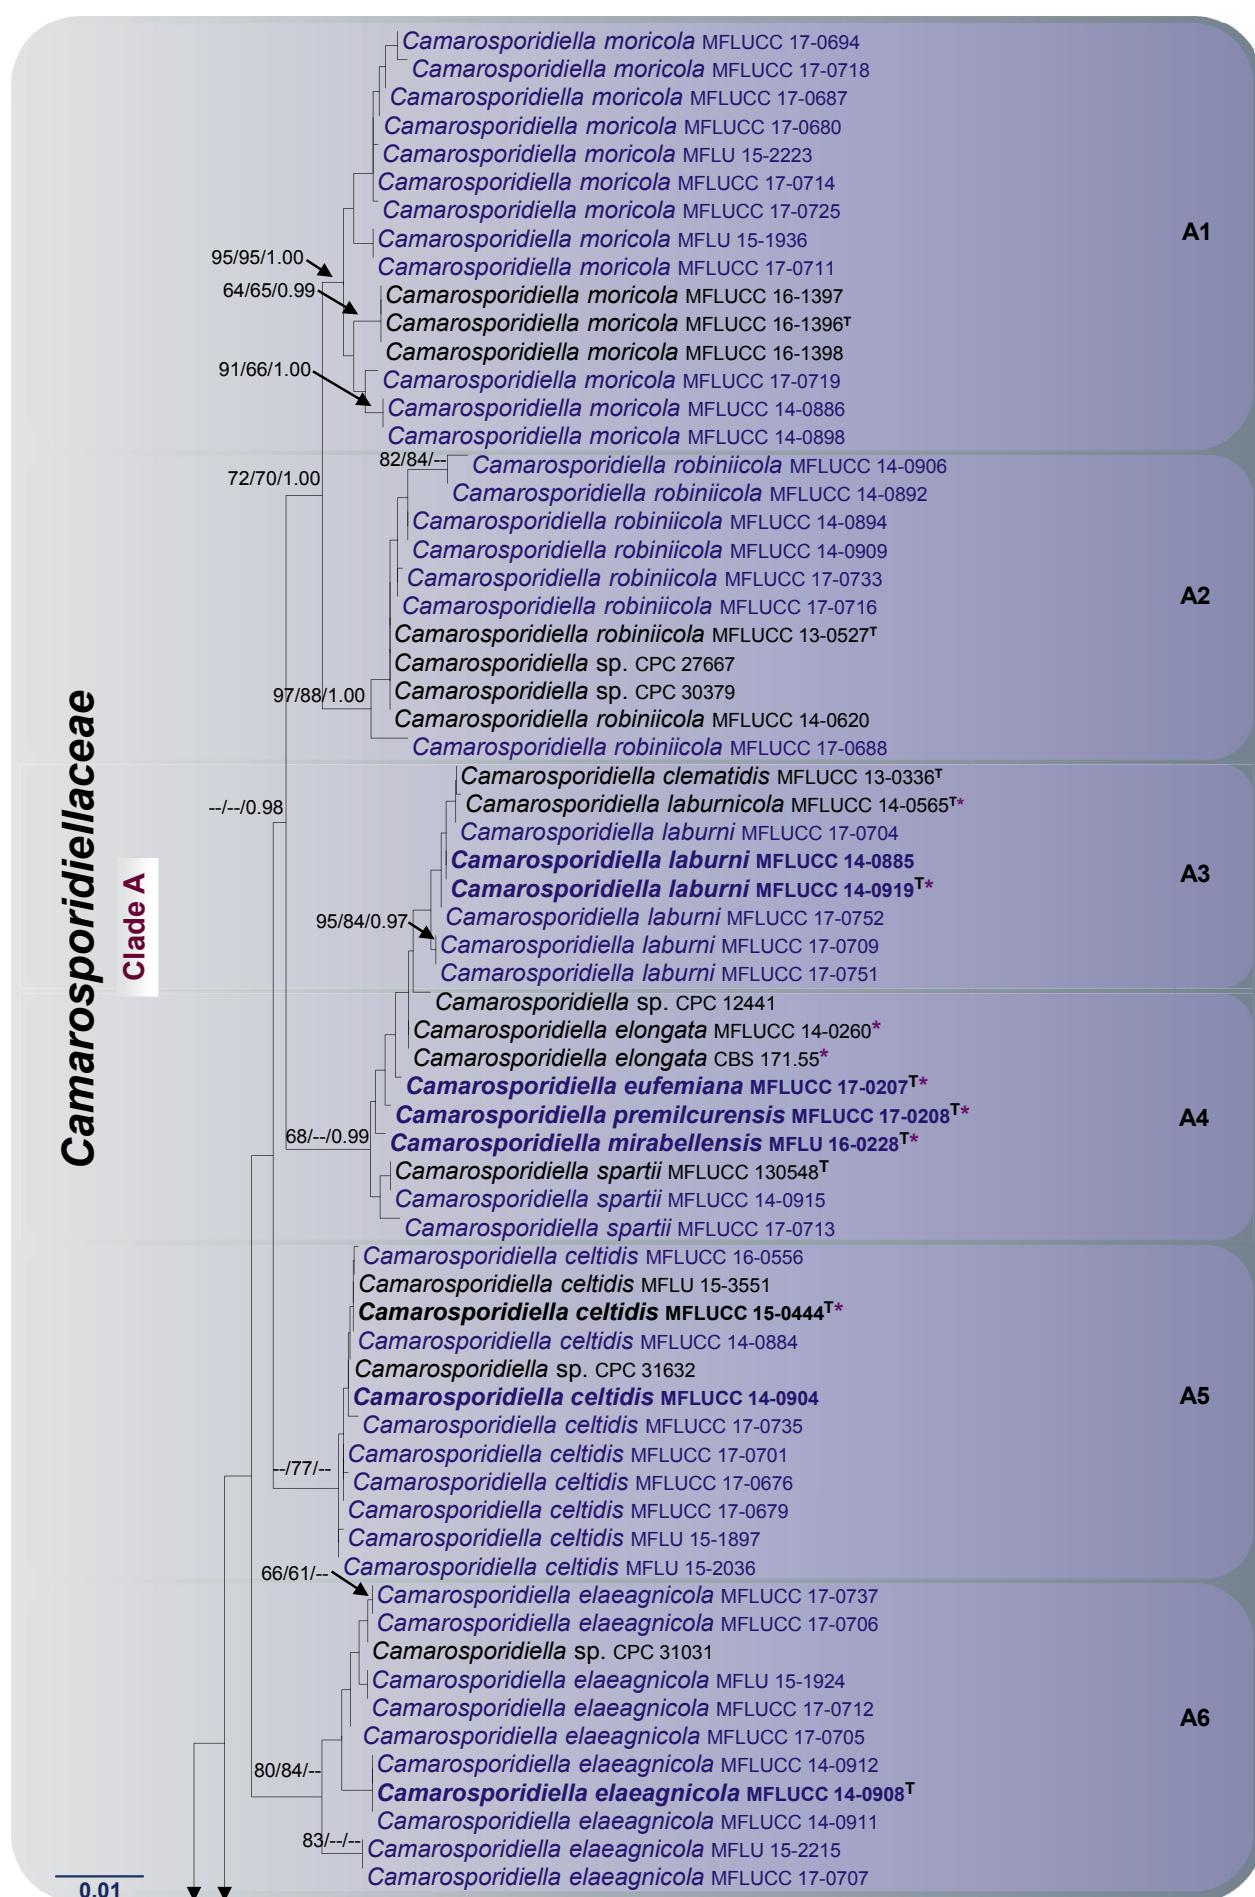

Fig. 1. RAxML tree based on a combined dataset of LSU, SSU, *tef1* and ITS partial sequences. Bootstrap support values for ML and MP equal to or greater than 60 %, Bayesian posterior probabilities (PP) equal to or greater than 0.95 are defined as ML/MP/PP above the nodes. Species used for morphological observation in this study are indicated in bold. Families, where known, and selected genera are indicated with coloured blocks. The tree is rooted to *Cyclothyriella rubronotata* (CBS 141486 & CBS 121892). The new isolates are in blue. Asterisk marks origin of isolates from single ascospore. The ex-type strains are noted with superscripted T. The scale bar represents the expected number of nucleotide substitutions per site.

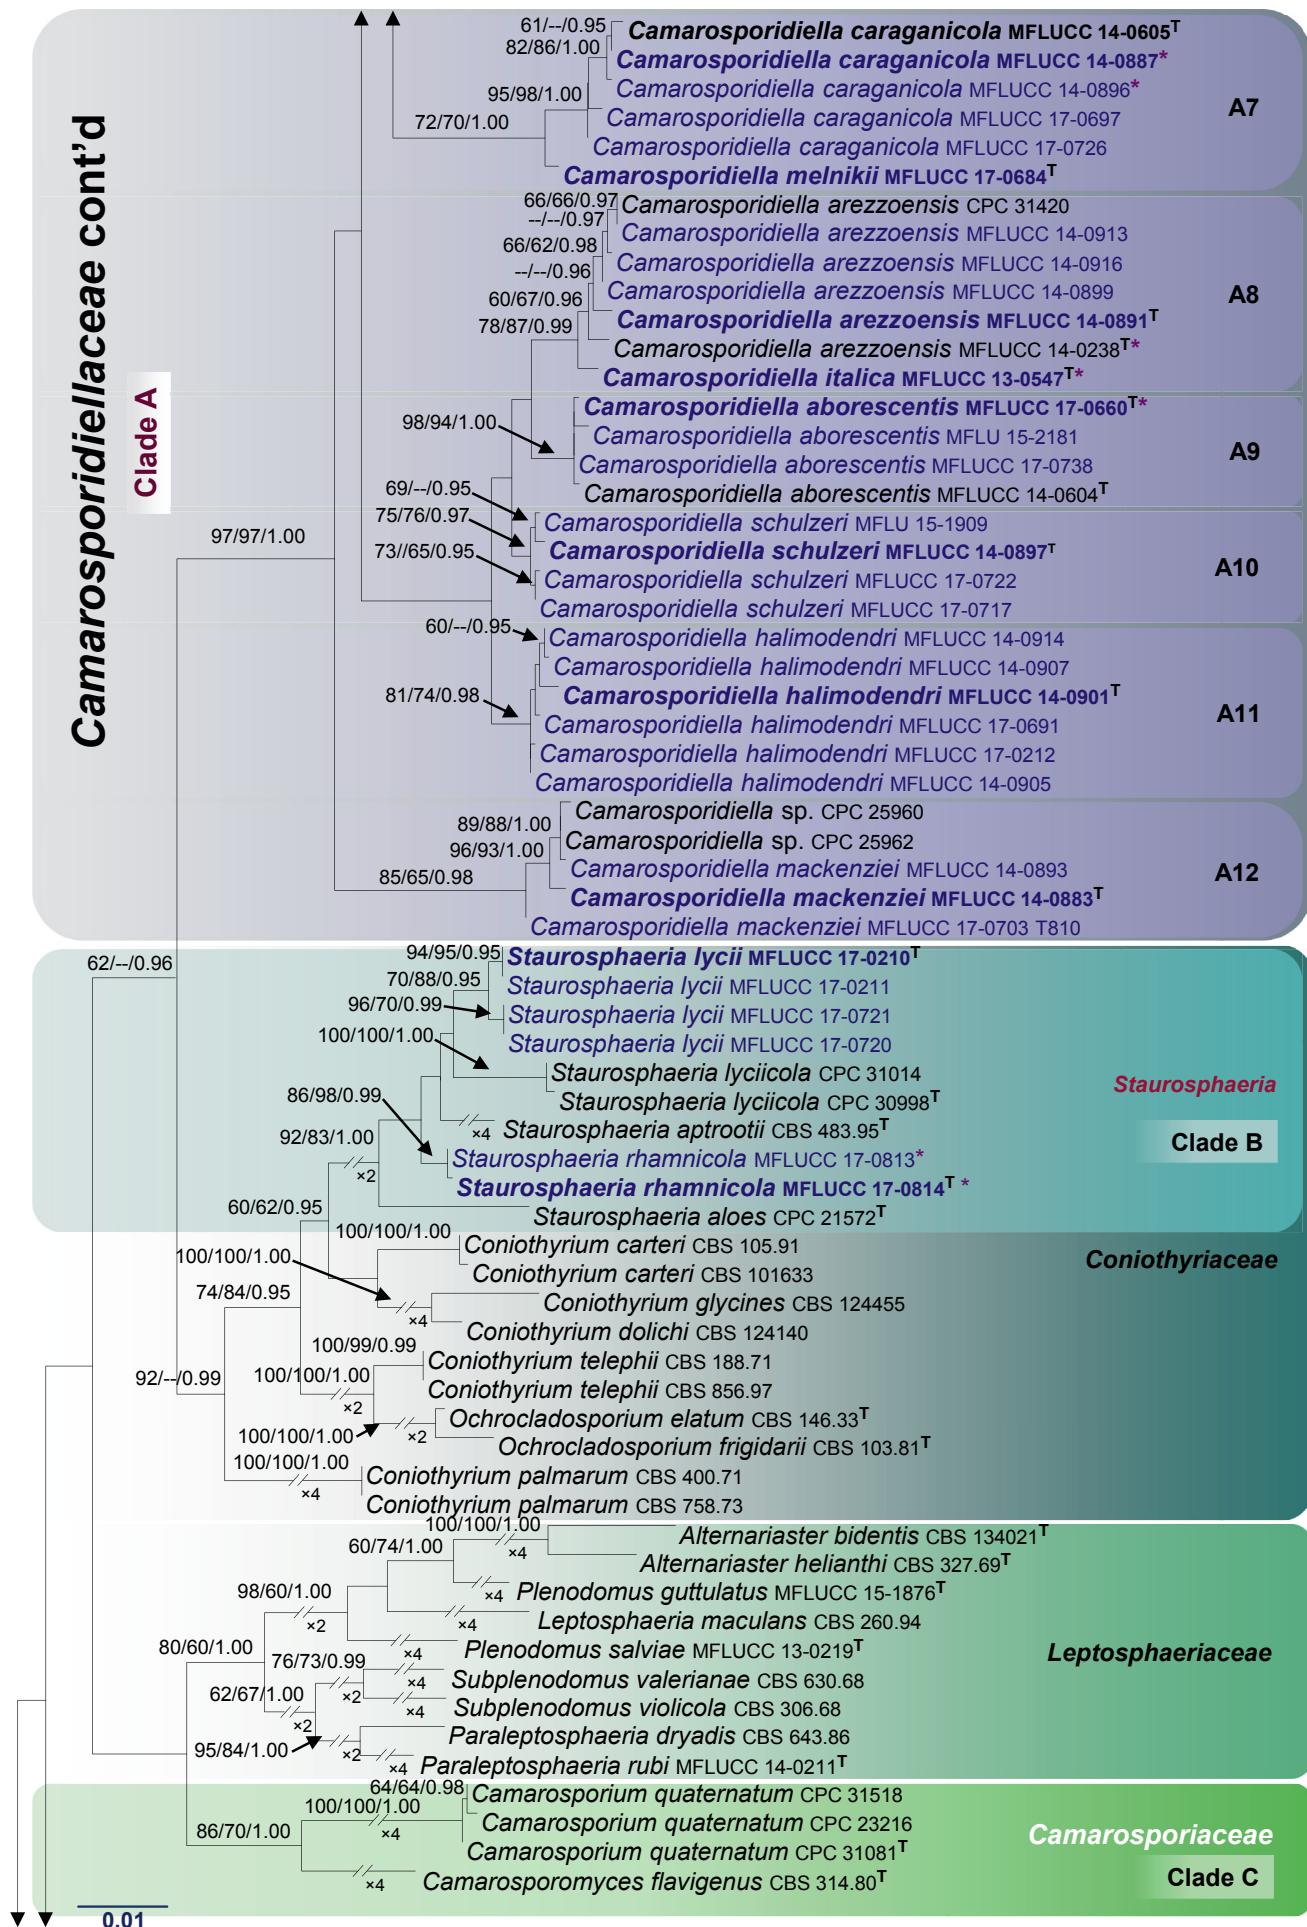

Fig. 1. (Continued).

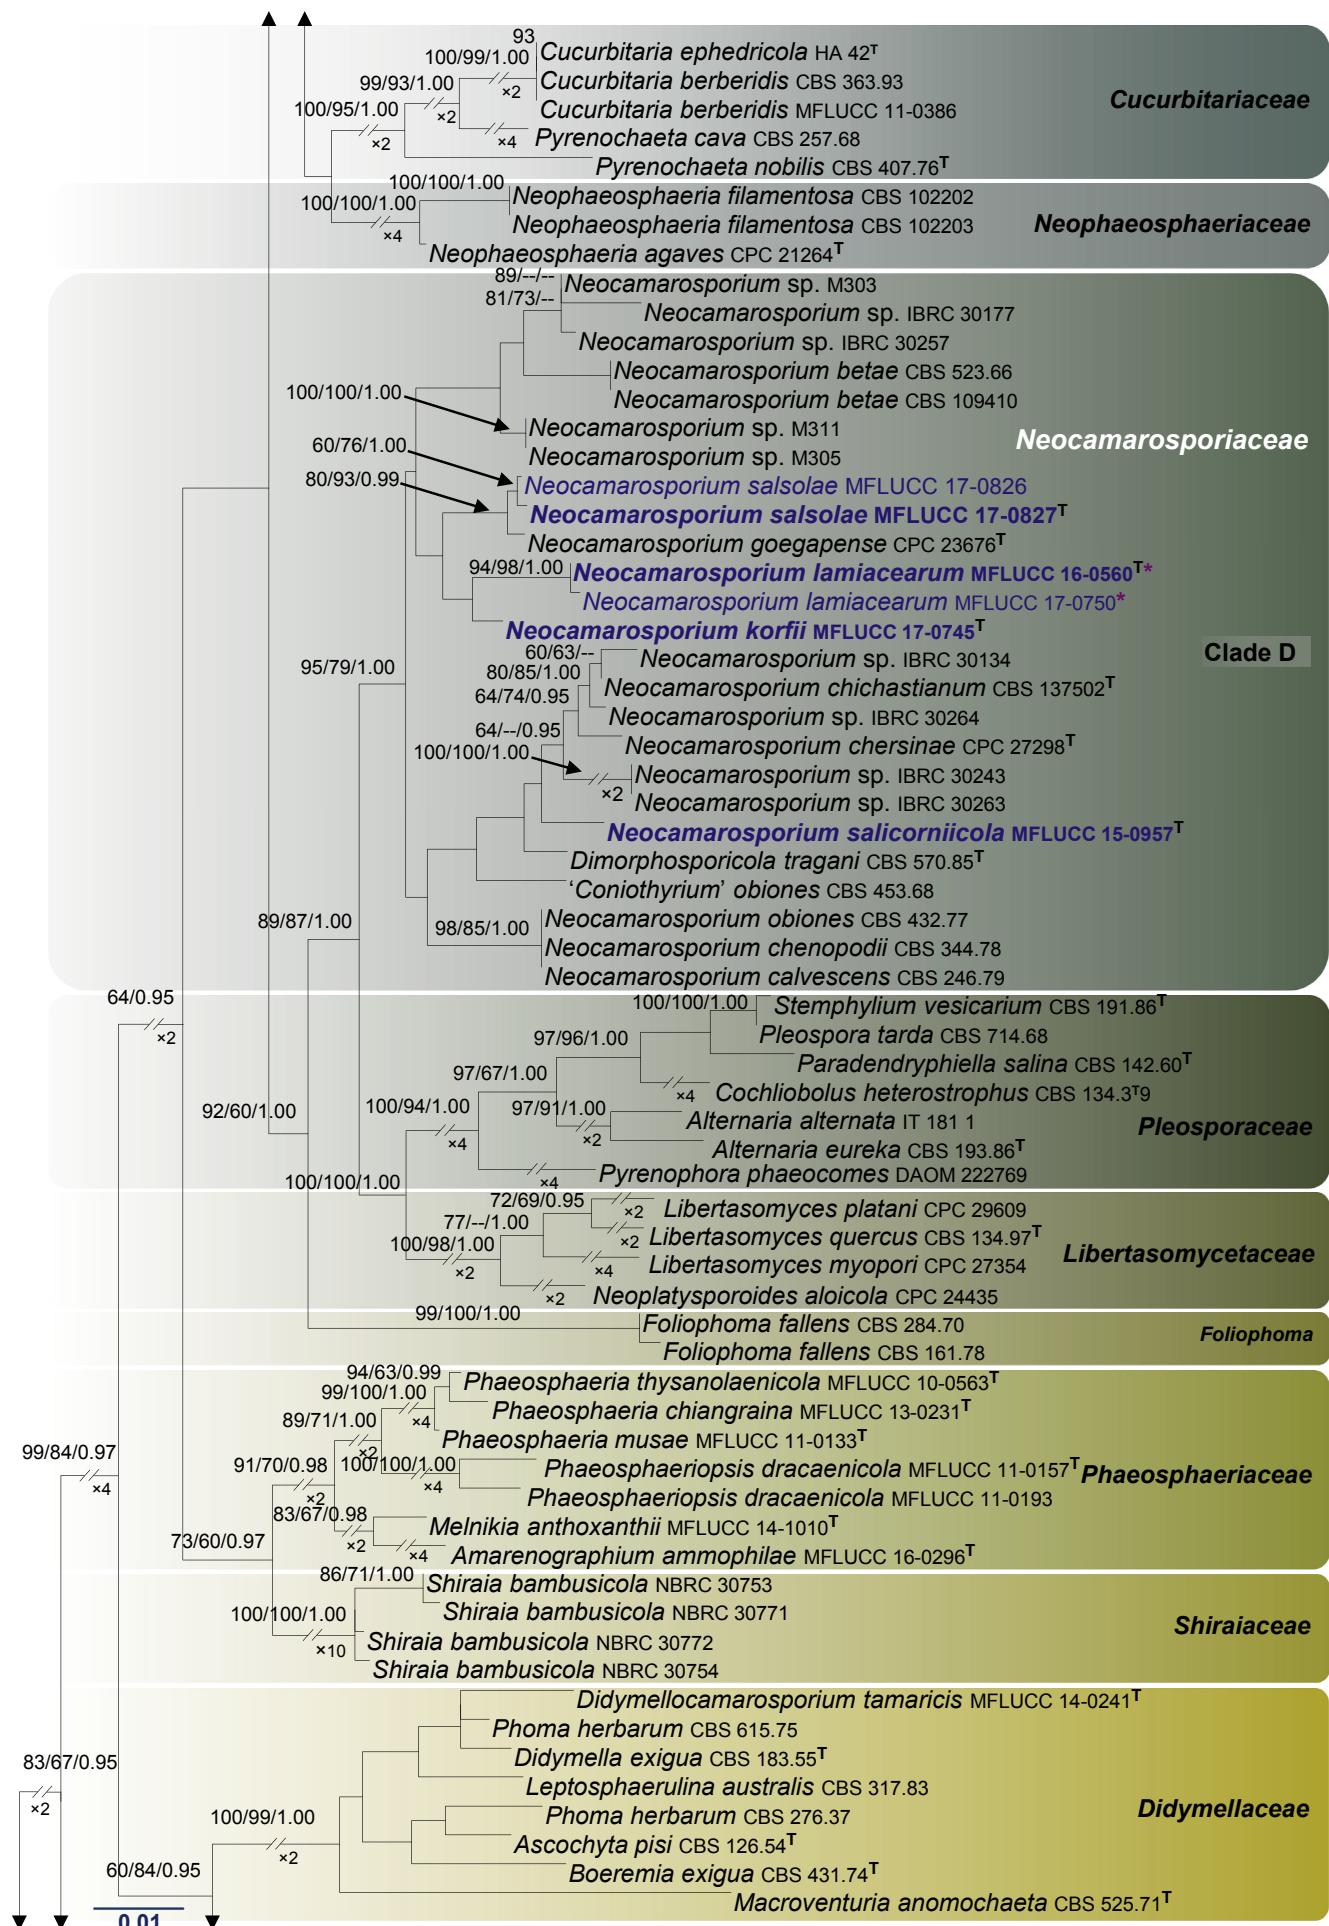

Fig. 1. (Continued).

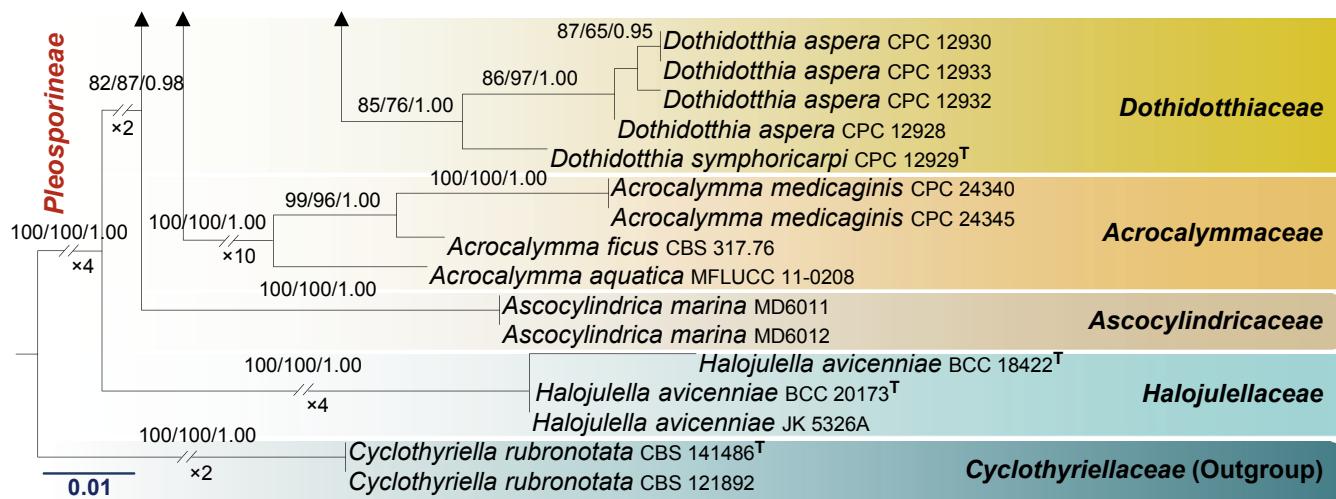

Fig. 1. (Continued).

ostiolate. Ostiole central, short. Peridium composed of blackish to dark brown cells of *textura angularis*, cells towards the inside lighter, composed of thin-walled cells of *textura angularis*. Hamathecium comprising numerous, branched septate, pseudoparaphyses. Asci 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate. Ascospores overlapping uniseriate, muriform, mostly ellipsoidal, 3–8-transversely septate, with 2–4 vertical septa, constricted at middle septum, initially hyaline, becoming brown at maturity, slightly paler, conical and narrow at the ends, not surrounded by a mucilaginous sheath.

Type species: *Camarosporidiella caraganicola* (Phukhams. et al.) Phukhams., Wanas. & K.D. Hyde.

Camarosporidiella caraganicola (Phukhams. et al.) Phukhams., Wanas. & K.D. Hyde, comb. nov. MycoBank MB821941; Facesoffungi number: FoF 03530. *Figs 3, 4*.

Basionym: *Camarosporium caraganicola* Phukhams. et al., Fungal Diversity 72: 156. 2015.

Saprobic on dead branches of *Caragana frutex*. Asexual morph: See Liu et al. (2015). Sexual morph: Ascomata 400–550 µm high, 450–500 µm diam ($\bar{x} = 436.2 \times 457.8$ µm, $n = 10$), black, superficial to semi-immersed, confluent, gregarious, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, rough or hairy, ostiolate. Ostiole central, short, slightly sunken, minute, inconspicuous on surface, smooth, with ostiolar canal filled with hyaline cells. Peridium 60–80 µm wide at the base, 50–70 µm wide in sides, comprising 8–10 layers, with outer layer heavily pigmented, thick-walled, comprising blackish to dark brown cells of *textura angularis*, cells towards inside lighter, with inner layer composed 3–4 layers, hyaline, flattened, thin-walled cells of *textura angularis*. Hamathecium comprising numerous, 2.5–3 µm ($n = 40$) wide, filamentous, branched, septate, pseudoparaphyses. Asci 150–190 × 10–15 µm ($\bar{x} = 170.8 \times 13.1$ µm, $n = 40$), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, rounded at apex with a minute ocular chamber. Ascospores 20–30 × 7–10 µm ($\bar{x} = 24.9 \times 8.7$ µm, $n = 50$), overlapping uniseriate, muriform, mostly ellipsoidal, 3–5-transversely septate, with 2–4 vertical septa, constricted at middle septum, initially hyaline, becoming brown at maturity, slightly paler, conical and narrow at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin white at first, greenish grey after 6 wk, reverse greenish grey, flat on the surface, without aerial mycelium.

Materials examined: Russia, Rostov region, Rostovna-Donu, BadiaTega, Botanical Garden of Southern Federal University, Systematic Arboretum, on dead twigs of *Caragana frutex* (Fabaceae), 26 Apr. 2014, T.S. Bulgakov T-046 (MFLU 14-0794, holotype; ex-type culture MFLUCC 14-0605; Rostov region, Rostov-na-Don city, Botanical garden of Southern Federal University, 47, 234635° N, 39, 656986° E, 3 Mar. 2014, T.S. Bulgakov T-005 (MFLU 17-0453, paratype; ex-paratype culture MFLUCC 14-0887 = CBS 143105); Rostov region, Oktyabrsky district, natural monument, 47, 5049392° N, 40, 1539564° E, 26 Apr. 2014, T.S. Bulgakov T-013, MFLU 17-0459, living culture MFLUCC 14-0896 = CBS 143106; Rostov region, Krasnosulinsky district, Donskoye forestry, Kabanya Balka, 47, 8643133° N, 40, 2421045° E, 28 Jun. 2015, T.S. Bulgakov T-538, MFLU 15-2242, living culture MFLUCC 17-0697 = CBS 143107, ibid. 18 Feb. 2016, T.S. Bulgakov T-1488, MFLU 16-1782, living culture MFLUCC 17-0726 = CBS 143108.

Notes: *Camarosporidiella caraganicola* (MFLUCC 14E-0605) is based on a strain derived from the asexual morph that was described by Liu et al. (2015). In this study, we have examined two specimens of the sexual morph of *Camarosporidiella caraganicola* (T-005 and T-013). These two taxa were collected from the same host (*Caragana frutex*) in the Rostov Region, Russia. By considering the identical host and statistical support, we conclude that these two taxa represent the holomorph of *Camarosporidiella caraganicola*. Also, we have observed another three specimens of the asexual morph of *Ca. caraganicola* (T-538 and T-1488). All strains of this species cluster together with significant statistical support of 95 % for ML, 98 % for MP and 1.00 for PP (Clade A7, Fig. 1).

Other accepted species

Camarosporidiella aborescens (Phukhams. et al.) Phukhams., Wanas. & K.D. Hyde, comb. nov. MycoBank MB821942; Facesoffungi number: FoF 03531. *Fig. 5*.

Basionym: *Camarosporium aborescens* Phukhams. et al., in Liu et al., Fungal Diversity 72: 151. 2015.

Saprobic on woody branches. Asexual morph: See Liu et al. (2015) for illustrations. Sexual morph: Ascomata 350–450 µm high, 500–600 µm diam ($\bar{x} = 406.4 \times 529.7$ µm, $n = 10$), black, superficial to semi-immersed, confluent, gregarious, sometimes

Fig. 2. *Camarosporidiella* spp. on different hosts. **A, B.** *Elaeagnus angustifolia*. **C, D.** *Caragana arborescens*. **E, F.** *Laburnum anagyroides*.

scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, rough or hairy, ostiolate. Ostiole central, short, slightly sunken, minute, inconspicuous on surface, smooth, with ostiolar canal filled with hyaline cells. Peridium 15–25 µm wide at the base, 25–50 µm wide in sides, comprising 6–10 layers, with outer layer heavily pigmented, thick-walled, comprising blackish to dark brown cells of *textura angularis*, cells towards inside lighter, with inner layer composed of 3–4 layers, hyaline, flattened, thin-walled cells of *textura angularis*. Hamathecium comprising numerous, 2–3 µm ($n = 40$) wide, filamentous, branched, septate, pseudoparaphyses. Asci 170–210 × 15–18 µm ($\bar{x} = 186.2 \times 16.1 \mu\text{m}$, $n = 40$), 8-spored,

bitunicate, fissitunicate, cylindrical, short-pedicellate, rounded at apex with a minute ocular chamber. Ascospores 28–32 × 12–13 µm ($\bar{x} = 29.9 \times 12.4 \mu\text{m}$, $n = 50$), overlapping uniseriate, muriform, mostly ellipsoidal, 5–7-transversely septate, with 1–2 vertical septa, constricted at middle septum, initially hyaline, becoming brown at maturity, slightly paler, conical and narrow at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, greenish-grey after 6 wk, reverse greenish-grey, flat on the

surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: **Italy**, Forlì-Cesena Province, near Predappio, on dead branches of *Colutea arborea* (Fabaceae), 25 Oct. 2015, E. Camporesi IT2674, MFLU 15-3630, living culture MFLUCC 17-0660. **Russia**, Rostov region, Rostov-on-Don city, Botanical Garden of Southern Federal University, Systematic Arboretum, parkland, 47,2350724° N, 39,6541643° E, on *Colutea orientalis*, 30 May 2015, T.S. Bulgakov T-477, MFLU 15-2181; on *Amorpha* sp., 14 Jun. 2016, T.S. Bulgakov NK076, MFLU 16-2387, living culture MFLUCC 17-0738.

Notes: *Camarosporidiella aborescens* is morphologically similar to *Camarosporium feurichii* in having black conidiomata and brown, smooth-walled, oblong, 3-transversely septate conidia and usually with one longitudinal septum (Liu et al. 2015). In this study, we add another three strains to *Camarosporidiella aborescens* from Italy and Russia. Altogether strains of this taxon cluster together with high statistical support of 98 % for ML, 94 % for MP and 1.00 for PP (Clade A9, Fig. 1).

***Camarosporidiella arezzoensis* (Tibpromma et al.) Wanas. & K.D. Hyde, comb. nov.** MycoBank MB821943; Facesoffungi number: FoF 03532. **Fig. 6.**

Basionym: *Camarosporium arezzoensis* Tibpromma et al., Saudi Journal of Biological Sciences 23: 2. 2016.

Saprobic or weakly necrotrophic on dead twigs and branches of *Amorpha fruticosa*. **Asexual morph:** **Conidiomata** pycnidial, 300–400 µm high, 300–350 µm diam ($\bar{x} = 347.9 \times 324.5$ µm, n = 10), solitary or gregarious, black, immersed, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, unilocular, with a papillate ostiolate. **Ostiole** 60–100 µm long, 100–150 µm diam ($\bar{x} = 82.2 \times 115.4$ µm, n = 6), central, long, smooth, ostiolar canal filled with hyaline or pale brown cells. **Pycnidial wall** multi-layered, 25–45 µm wide at the base, 25–35 µm wide in sides, thick, comprising 5–6 layers, outer layer heavily pigmented, thick-walled, comprising blackish or to dark reddish-brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 1–2 layers, hyaline, thin-walled cells of *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Macroconidiogenous cells** enteroblastic, annellidic, doliiform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. **Macroconidia** 20–28 × 6–9 µm ($\bar{x} = 24 \times 7.8$ µm; n = 40), cylindrical, straight to slightly curved, rounded at both ends, 4–7-transverse septate, with 1–2-longitudinal septa, muriform, smooth, brown to blackish-brown. **Microconidiogenous cells** intermingled with macroconidiogenous cells, hyaline, discrete, enteroblastic with percurrent annellidic, ampulliform to subcylindrical. **Microconidia** 5–7.5 × 3.5–4.5 µm ($\bar{x} = 6.3 \times 4$ µm; n = 25), hyaline, round to

oblong or ellipsoidal, with a few small guttules. *Sexual morph*: See Tibpromma et al. (2015).

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, dirty white, reverse creamy grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: **Russia**, Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Lower Park, 47,2313935° N, 39,6648932° E, on *Amorpha fruticosa* (Fabaceae), 14 Apr. 2013, T.S. Bulgakov T-009 (MFLU 17-0455, living culture MFLUCC 14-0891); Azov district, Delta of Don river, sand dunes near Polushkin village, 47,1981111° N, 39,4148684° E, on *Cytisus borysthenicus* (Fabaceae), 8 May 2014, T.S. Bulgakov T-064, MFLU 17-0475, living culture MFLUCC 14-0913 = CBS 143103; Rostov-on-Don city, Botanical garden of Southern Federal University, Systematic Arboretum, 47,2360559° N, 39,6555591° E, on *Cytisus austriacus* (Fabaceae), 8 May 2014, T.S. Bulgakov T-072, MFLU 17-0478, living culture MFLUCC 14-0916 = CBS 143103; Rostov-on-Don city, Botanical garden of Southern Federal University, Systematic Arboretum, 47,2360559° N, 39,6555591° E, on *Cytisus austriacus*, 5 Mar. 2014, T.S. Bulgakov T-016, MFLU 17-0462, living culture MFLUCC 14-0899 = CBS 143102.

Notes: *Camarosporidiella arezzoensis* was reported as a sexual morph and is similar to *Cucurbitaria* species in having long cylindrical ascospores and narrowly fusiform, muriform ascospores, being 5–7-transversely septate, with 4–6 vertical septa (Tibpromma et al. 2015). An asexual morph was undetermined. In this study, we introduce the asexual morph of *Ca. arezzoensis* with four new collections from Russia on *Amorpha fruticosa* and *Cytisus austriacus*. Strains of *Camarosporidiella arezzoensis* cluster together with 60 % for ML, 67 % for MP and 0.96 for PP support (Clade A8, Fig. 1). *Camarosporium amorphae* (= *Cucurbitaria amorphae*) and *Cm. amorphicola* are also found on *Amorpha fruticosa* in Canada and Central Asia (Farr & Rossman 2017), but *Cm. amorphae* (20–24 × 9 µm, 4–5 transverse septa) has fewer transverse septa (Saccardo 1883) compared to the asexual morph of *Camarosporidiella arezzoensis* (20–28 × 6–9 µm, and 4–7 transverse septa). Records are lacking for comparison of *Camarosporium amorphicola* with our new taxon. Our collection differs from known other members in *Camarosporidiella* in having cylindrical conidia.

***Camarosporidiella celtidis* (Shear) Thambug., Wanas. & K.D. Hyde, comb. nov.** MycoBank MB821945; Facesoffungi number: FoF 03533. Figs 7, 8.

Basionym: *Cucurbitaria celtidis* Shear, Bull. Torrey bot. Club 29: 451. 1902.

Synonym: *Camarosporium uniseriatum* Thambug. et al., Stud. Fung. 1: 94. 2016.

Necrotrophic or saprobic on dead twigs and thin branches. **Asexual morph:** Conidiomata pycnidial, 300–350 µm high, 350–450 µm diam ($\bar{x} = 337.1 \times 392.7$ µm, n = 10), solitary or gregarious, black, immersed to semi-eruptive, unilocular. **Pycnidial wall** multi-layered, 20–25 µm wide at the base, 25–30 µm wide in sides, thick, comprising 3–4 layers, outer layer heavily pigmented, thick-walled, comprising blackish or to dark reddish-brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 3–4 layers, hyaline, thick-walled cells of *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Conidiogenous cells** enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-

walled, and formed from the inner layer of pycnidium wall. **Conidia** 15–20 × 6–8 µm ($\bar{x} = 16.8 \times 6.9$ µm; n = 40), oblong, straight, rounded at both ends, sometimes narrowly rounded ends, 2–3-transversely septate, without longitudinal septa, smooth-walled, initially hyaline, becoming brown to dark brown at maturity. **Sexual morph:** Ascomata black, semi-immersed, becoming erumpent, scattered, solitary to gregarious, globose to subglobose, coriaceous, rough or hairy, ostiolate. **Ostiole** central, short, ostiolar canal filled with hyaline to lightly pigmented pseudoparenchymatous cells. **Peridium** comprising several layers, outer layers heavily pigmented, thick-walled, comprising blackish to dark brown cells of *textura angularis*, inner layers composed of hyaline, thin-walled cells of *textura angularis*. **Hamathecium** comprising 1–3 µm wide, numerous, filamentous, septate, pseudoparaphyses. **Asci** 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded, with an ocular chamber. **Ascospores** uniseriate, slightly overlapping, initially hyaline, becoming dark brown at maturity, ellipsoid, oblong to fusoid, straight, muriform, with 3–5 transverse septa, and 1–2(–3) longitudinal septa, deeply constricted at the central septum, with rounded or acute ends, smooth-walled, without a mucilaginous sheath (Thambugala et al. 2016).

Materials examined: **Russia**, Rostov Region, Rostov-on-Don city, Botanical Garden of Southern Federal University, Higher Park, on twigs and branches of *Celtis occidentalis* (Cannabaceae), 5 Mar. 2014, T.S. Bulgakov T-767, MFLU 15-2912, living culture MFLUCC 17-0701 = CBS 143112.

Notes: *Cucurbitaria celtidis* was introduced by Shear (1902) from *Celtis occidentalis*. Thambugala et al. (2016) placed this species in the genus *Camarosporium* based on DNA sequence data from a fresh collection and introduced *Cm. uniseriatum*. However, in the present study, we accommodate *Cucurbitaria celtidis* in the new genus *Camarosporidiella* and the asexual morph of the species is described and illustrated (Fig. 7). Nine new isolates cluster in the *Ca. celtidis* clade (Subclade A5, Fig. 1), and they are differing from known other members in *Camarosporidiella* in having conidia without longitudinal septa. However, this subclade is only moderately supported ≤ 60 % ML & 77 % MP and ≤ 0.95 PP.

***Camarosporidiella clematidis* (Wijayaw. et al.) Wijayaw., Wanas. & K.D. Hyde, comb. nov.** MycoBank MB821946; Facesoffungi number: FoF 03534.

Basionym: *Camarosporium clematidis* Wijayaw. et al., Phytotaxa 183: 19. 2014.

Fig. 7. Sexual morph of *Camarosporidiella celtidis* (MFLU 17-469). **A.** Appearance of ascomata on host substrate. **B.** Section of ascoma. **C.** Pseudoparaphyses. **D–E.** Asci. **F–I.** Ascospores. Scale bars: B = 100 µm; C = 10 µm; D, E = 20 µm; F–I = 10 µm.

Illustrations: See [Wijayawardene et al. \(2014a\)](#).

Notes: [Wijayawardene et al. \(2014a\)](#) introduced this species from *Clematis vitalba* in Italy. The sexual morph has not been reported. In this study *Camarosporidiella clematidis* groups with *Ca. laburnicola* ([Tibpromma et al. 2017](#)), which was reported as the sexual morph. This subclade (Subclade A3, [Fig. 1](#)) is not supported and therefore the lifecycle link between these two taxa is ambiguous.

Camarosporidiella elaeagnicola Wanas., Bulgakov & K.D. Hyde sp. nov. MycoBank MB821947; Facesoffungi number: FoF 03535. [Fig. 9](#).

Etymology: Named after the host genus from which it was collected, *Elaeagnus*.

Necrotrophic on dying branches of *Elaeagnus angustifolia*. **Asexual morph:** Conidiomata pycnidial, 300–500 µm high, 300–550 µm diam ($\bar{x} = 384.2 \times 410.8$ µm, n = 10), solitary or gregarious, black, immersed, uni- to multi-locular, with a papillate ostiole. **Pycnidial wall** multi-layered, 15–20 µm wide at the base, 30–40 µm wide in sides, comprising 5–8 layers, with heavily pigmented outer layer, thick-walled, comprising blackish to dark brown cells of *textura angularis*, with lighter cells towards the inside, with inner layer composed of 2–4 layers, hyaline, thin-walled cells of *textura angularis*. **Macroconidiophores** reduced to conidiogenous cells. **Macroconidiogenous cells** enteroblastic with percurrent annellations, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. **Macroconidia** 18–25 × 9–13 µm ($\bar{x} = 19.5 \times 10.8$ µm; n = 30), oblong, straight to slightly curved, rounded at both ends, 2–3-transversely septate, with one longitudinal septum,

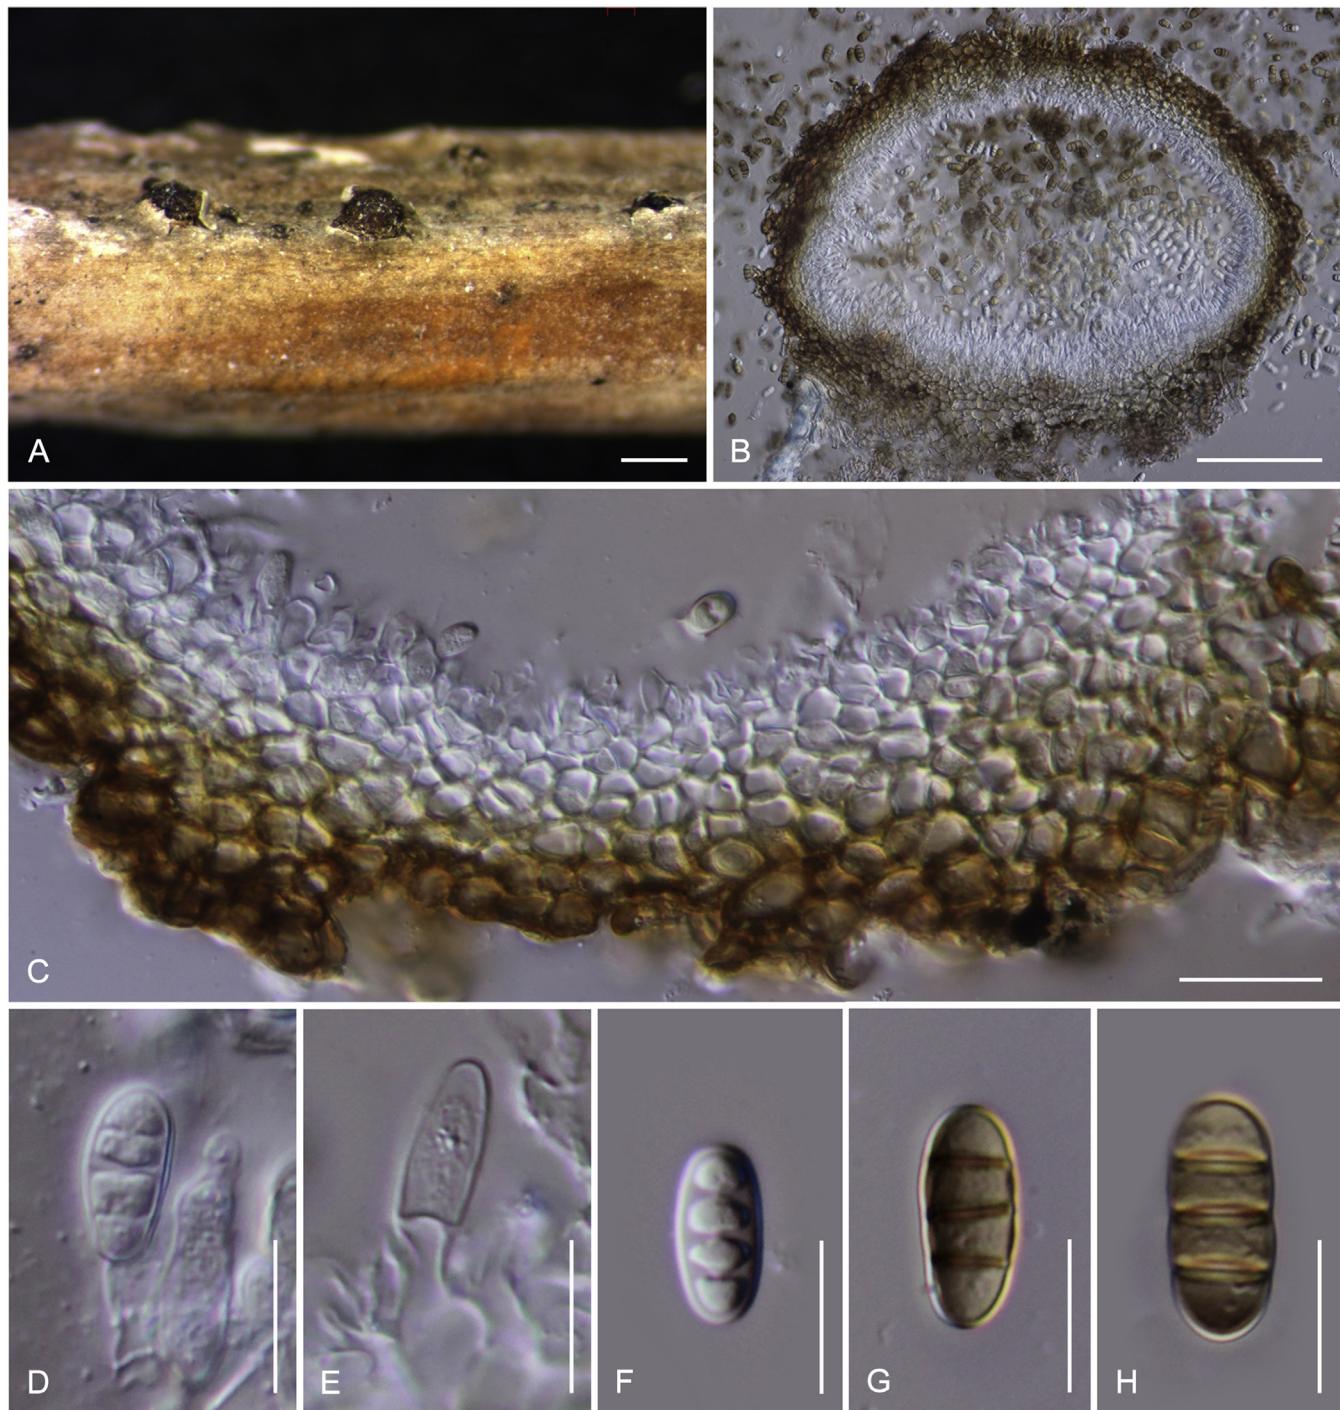

Fig. 8. Asexual morph of *Camarosporidiella celtidis* (MFLU 17-0466). **A.** Conidiomata on host surface. **B.** Vertical section through conidioma. **C.** Conidiomata wall. **D–E.** Conidiogenous cells producing conidia. **F–H.** Conidia. Scale bars: A = 500 µm; B = 100 µm; C = 20 µm; D–H = 10 µm.

muriform, smooth, pale to dark brown. *Microconidiogenous cells* intermingled with macroconidiogenous cells, hyaline, discrete, enteroblastic with percurrently annellidic, ampulliform to sub-cylindrical. *Microconidia* $5\text{--}6.5 \times 3.5\text{--}4.5 \mu\text{m}$ ($\bar{x} = 5.9 \times 4.1 \mu\text{m}$; $n = 25$), hyaline, round to oblong or ellipsoidal, with a few small guttules. *Sexual morph:* Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, white at the centre, greenish grey towards margin, reverse greenish-grey, flat on the surface, without aerial mycelium.

Materials examined: Russia, Rostov Region, Oktyabrsky District, Shakhty city, near Grushevsky pond, shelterbelt artificial forest, 47,7250642° N, 40,2564812° E, on *Elaeagnus angustifolia* (Elaeagnaceae), 18 May 2014, T.S.

Bulgakov T-051 (MFLU 17-0470, **holotype**, ex-type culture MFLUCC 14-0908 = CBS 143113); Rostov-on-Don city, Botanical garden of Southern Federal University, Higher Park, 47,2360559° N, 39, 6555591° N, on *Elaeagnus angustifolia*, 26 Mar. 2014, T.S. 2382, living culture MFLUCC 17-0712; *ibid.* 14 Jun. 2016, T-NK067, MFLU 15-2962, living culture MFLUCC 17-0707.

Notes: In our phylogenetic analyses, 11 strains of *Camarosporidiella elaeagnicola* cluster together with 80 % ML and 84 % MP support (Subclade A6, Fig. 1). Ten of these isolations were collected on *Elaeagnus angustifolia* from Russia and one from *Elaeagnus rhamnoides* in Germany. *Camarosporium*

elaeagnellum and *Cm. elaeagni* have also been found on *Elaeagnus angustifolia* from California, Canada and Ukraine (Farr & Rossman 2017). The relationship between these *Camarosporium* spp. with *Camarosporidiella elaeagnicola* cannot be investigated due to lack of morphological and molecular data for *Camarosporium elaeagnellum* and *Cm. elaeagni*. Thus, we introduce *Camarosporidiella elaeagnicola* as a new species.

Camarosporidiella elongata (Fr.) Wanas., Wijayaw. & K.D. Hyde, **comb. nov.** MycoBank MB821948; Facesoffungi number: FoF 03536.

Basionym: *Sphaeria elongata* Fr., Observationes mycologicae 1: 175. 1815.

Synonyms: *Cucurbitaria elongata* (Fr.) Grev., Scott. crypt. fl.: pl. 195. 1826.

Gibberidea elongata (Fr.) Kuntze, Revisio generum plantarum 3: 481. 1898.

Note: See Mirza (1968) for further details on *Camarosporidiella elongata* (= *Cucurbitaria elongata*).

Camarosporidiella eufemiana Wanas., Camporesi & K.D. Hyde, **sp. nov.** MycoBank MB821949; Facesoffungi number: FoF 03537. **Fig. 10.**

Etymology: *eufemiana*, due to its occurrence in Santa Eufemia, Italy.

Saprobic on dead branches of *Cytisus* sp. **Asexual morph:** Undetermined. **Sexual morph:** Ascomata 350–400 µm high, 450–550 µm diam ($\bar{x} = 376.8 \times 496.4$ µm, n = 10), black, semi-erumpent to superficial, solitary or gregarious, globose, ostiolate. Ostiole short papillate central, slightly sunken, minute and inconspicuous at the surface, smooth, with ostiolar canal filled with hyaline to brown cells. Peridium 40–50 µm wide at the base, 40–70 µm wide in sides, thick, comprising 6–8 layers, with heavily pigmented outer layer, thick-walled, comprising blackish to dark brown elongated cells of *textura angularis*, cells towards the inside lighter, with inner layer composed 2–3 layers, hyaline, flattened, thin-walled cells of *textura angularis*. Hamathecium comprising numerous, 2.5–3.5 µm (n = 30) wide, filamentous, branched, septate, pseudoparaphyses. Ascii 130–150 × 14–15 µm ($\bar{x} = 142.4 \times 14.5$ µm, n = 20), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, rounded at apex with a minute ocular chamber. Ascospores 20–25 × 10–12 µm ($\bar{x} = 21.9 \times 10.3$ µm, n = 30), overlapping uniseriate or sometimes biseriate, muriform, mostly ellipsoidal, 3–5-transversely septate, with one longitudinal septum, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming brown at maturity, asymmetrical, upper part wider than lower part, conical and narrowly rounded at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 3 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin creamy to pale brown centre and dirty white towards the margin after 6 wk, reverse iron, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Material examined: **Italy**, Forlì-Cesena [FC], Premilcuore, Santa Eufemia, on dead aerial branches of *Cytisus* sp. (Fabaceae), 3 Jan. 2014, E. Camporesi IT1621 (MFLU 16-0182, **holotype**, ex-type culture MFLUCC 17-0207 = CBS 143116).

Notes: *Camarosporidiella eufemiana* morphologically resembles other sexual members in this genus in having similar asci and ascospore shapes. In the phylogenetic analyses, *Ca. eufemiana* groups as a sister taxon to *Ca. elongata* but with no statistical support (Subclade A4, **Fig. 1**). However, *Ca.*

eufemiana is different from *Ca. elongata* in having longer asci (140–225 µm, Mirza 1968) with a long pedicel, while *Ca. eufemiana* has comparatively shorter asci (130–150 µm) with a short pedicel. *Camarosporidiella laburni* (= *Cucurbitaria laburni*) and *Cucurbitaria spartii* are also reported from *Cytisus* sp. (Mirza 1968). *Camarosporidiella laburni* (Subclade A3, **Fig. 1**) is phylogenetically distinct from *Ca. eufemiana* in this study. There is no molecular data available for *Cucurbitaria spartii* and its relationship to *Camarosporidiella eufemiana* cannot be resolved. However, *Ca. eufemiana* has shorter asci (130–150 µm) than *Cucurbitaria spartii* (150–240 µm, Mirza 1968).

Camarosporidiella halimodendri Wanas., Bulgakov & K.D. Hyde, **sp. nov.** MycoBank MB821950; Facesoffungi number: FoF 03538. **Fig. 11.**

Etymology: Named after the host genus from which it was collected, *Halimodendron*.

Saprobic or **weakly pathogenic** on dead branches of *Halimodendron halodendron*. **Asexual morph:** Conidiomata pycnidial, 500–600 µm high, 350–600 µm diam ($\bar{x} = 480.4 \times 496.7$ µm, n = 10), solitary or gregarious, black, immersed, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, unilocular, with a papillate ostiolate. Ostiole 100–200 µm long, 80–120 µm diam ($\bar{x} = 169.2 \times 93.4$ µm, n = 6), central, long, smooth, sometimes ostiolar canal filled with hyaline or pale brown cells. **Pycnidial wall** multi-layered, 25–35 µm wide at the base, 35–45 µm wide in sides, thick, comprising 5–6 layers, outer layer heavily pigmented, thick-walled, comprising blackish to dark reddish-brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 1–2 layers, hyaline, thin-walled cells of *textura angularis*. **Conidiophores** reduced to conidiogenous cells. **Macroconidiogenous cells** enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. **Macroconidia** 18–25 × 8–12 µm ($\bar{x} = 21.5 \times 10.7$ µm; n = 40), oblong, straight to slightly curved, rounded at both ends, sometimes narrowly rounded ends, 4–6-transverse septate, with 1–2 longitudinal septa, with 2–4 oblique septa, muriform, smooth-walled, brown to dark brown. **Microconidiogenous cells** intermingled with macroconidiogenous cells, hyaline, discrete, enteroblastic with percurrent annellidic, ampulliform to subcylindrical. **Microconidia** 4.5–7.5 × 3.5–4.5 µm ($\bar{x} = 6.5 \times 3.9$ µm; n = 25), hyaline, round to oblong or ellipsoidal, with a few small guttules. **Sexual morph:** Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, white, reverse cream-grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: **Russia**, Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Systematic Arboretum, 47,2360559° N, 39,6555591° E, on dying twigs and shrubs *Halimodendron halodendron* (Fabaceae), 8 May 2013, T.S. Bulgakov T-018 (MFLU 17-0463, **holotype**, ex-type culture, MFLUCC 14-0901 = CBS 143117); *ibid.* 26 Mar. 2014, T-041 (MFLU 17-0467, **paratype**, ex-paratype culture, MFLUCC 14-0905); Rostov Region, Shakhty city, near Grushevsky pond, stony steppe, 47,7237362° N, 39,2551937° E, on dead twigs of *Caragana frutex* (Fabaceae), 18 May 2014, T.S. Bulgakov T-050, MFLU 17-0469, living culture MFLUCC 14-0907 = CBS 143118;

Fig. 10. *Camarosporidiella eufemiana* (MFLU 16-0182, holotype) **A.** Appearance of ascomata on host substrate. **B.** Section of ascoma. **C.** Pseudoparaphyses. **D–F.** Ascii. **G–I.** Ascospores. Scale bars: A = 500 µm; B = 100 µm; C = 5 µm; D–F = 20 µm; G–I = 10 µm.

Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Systematic Arboretum, 47,2360559° N, 39,6555591° E, on dead twigs of *Cytisus podolicus* (Fabaceae), 8 May 2014, T.S. Bulgakov T-066, MFLU 17-0476, living culture MFLUCC 14-0914; Rostov Region, Shakhty city, coal heap of former coal mine 'Proletarian dictatorship', 47,7104110° N, 40,2627254° E, on dead twigs of *Lycium barbarum* (Solanaceae), 21 May 2015, T.S. Bulgakov T-419, MFLU 15-2123, living culture MFLUCC 17-0212 = CBS 143119.

Notes: *Camarosporium halimi* (12–16 × 9–13 µm, 2–3 transverse septa) has also been found on *Halimodendron halodendron* from Iran (Farr & Rossman 2017), but it has smaller conidia with fewer transverse septa (Saccardo 1906) compared to *Camarosporidiella halimodendri* (8–25 × 8–12 µm, 4–6 transverse septa). In this study, we refer six strains to *Ca. halimodendri* (Subclade A11, Fig. 1), which group together with 81 % ML, 74 % MP, 0.98 PP statistical support and share similar morphologies.

***Camarosporidiella italicica* Wanas., Camporesi & K.D. Hyde, sp. nov.** MycoBank MB821951; Facesoffungi number: FoF 03539. Fig. 12.

Etymology: *italicica*, due to its occurrence in Italy.

Saprobic on dead branches of *Coronilla emerus*. **Asexual morph:** Undetermined. **Sexual morph:** Ascomata 400–450 µm high, 550–600 µm diam ($\bar{x} = 436.2 \times 457.8$ µm, n = 10), black, immersed to semi-eruptive, solitary or gregarious, globose, with an ostiole comprising greenish grey setae. Ostiole 60–90 µm long, 30–45 µm diam ($\bar{x} = 76.2 \times 36.4$ µm, n = 6) central, short, slightly sunken, minute and inconspicuous on the surface, smooth, ostiolar canal filled with hyaline to brown cells. Peridium 20–30 µm wide at the base, 40–50 µm wide in sides, thick, comprising 5–8 layers, outer layer heavily pigmented, thick-

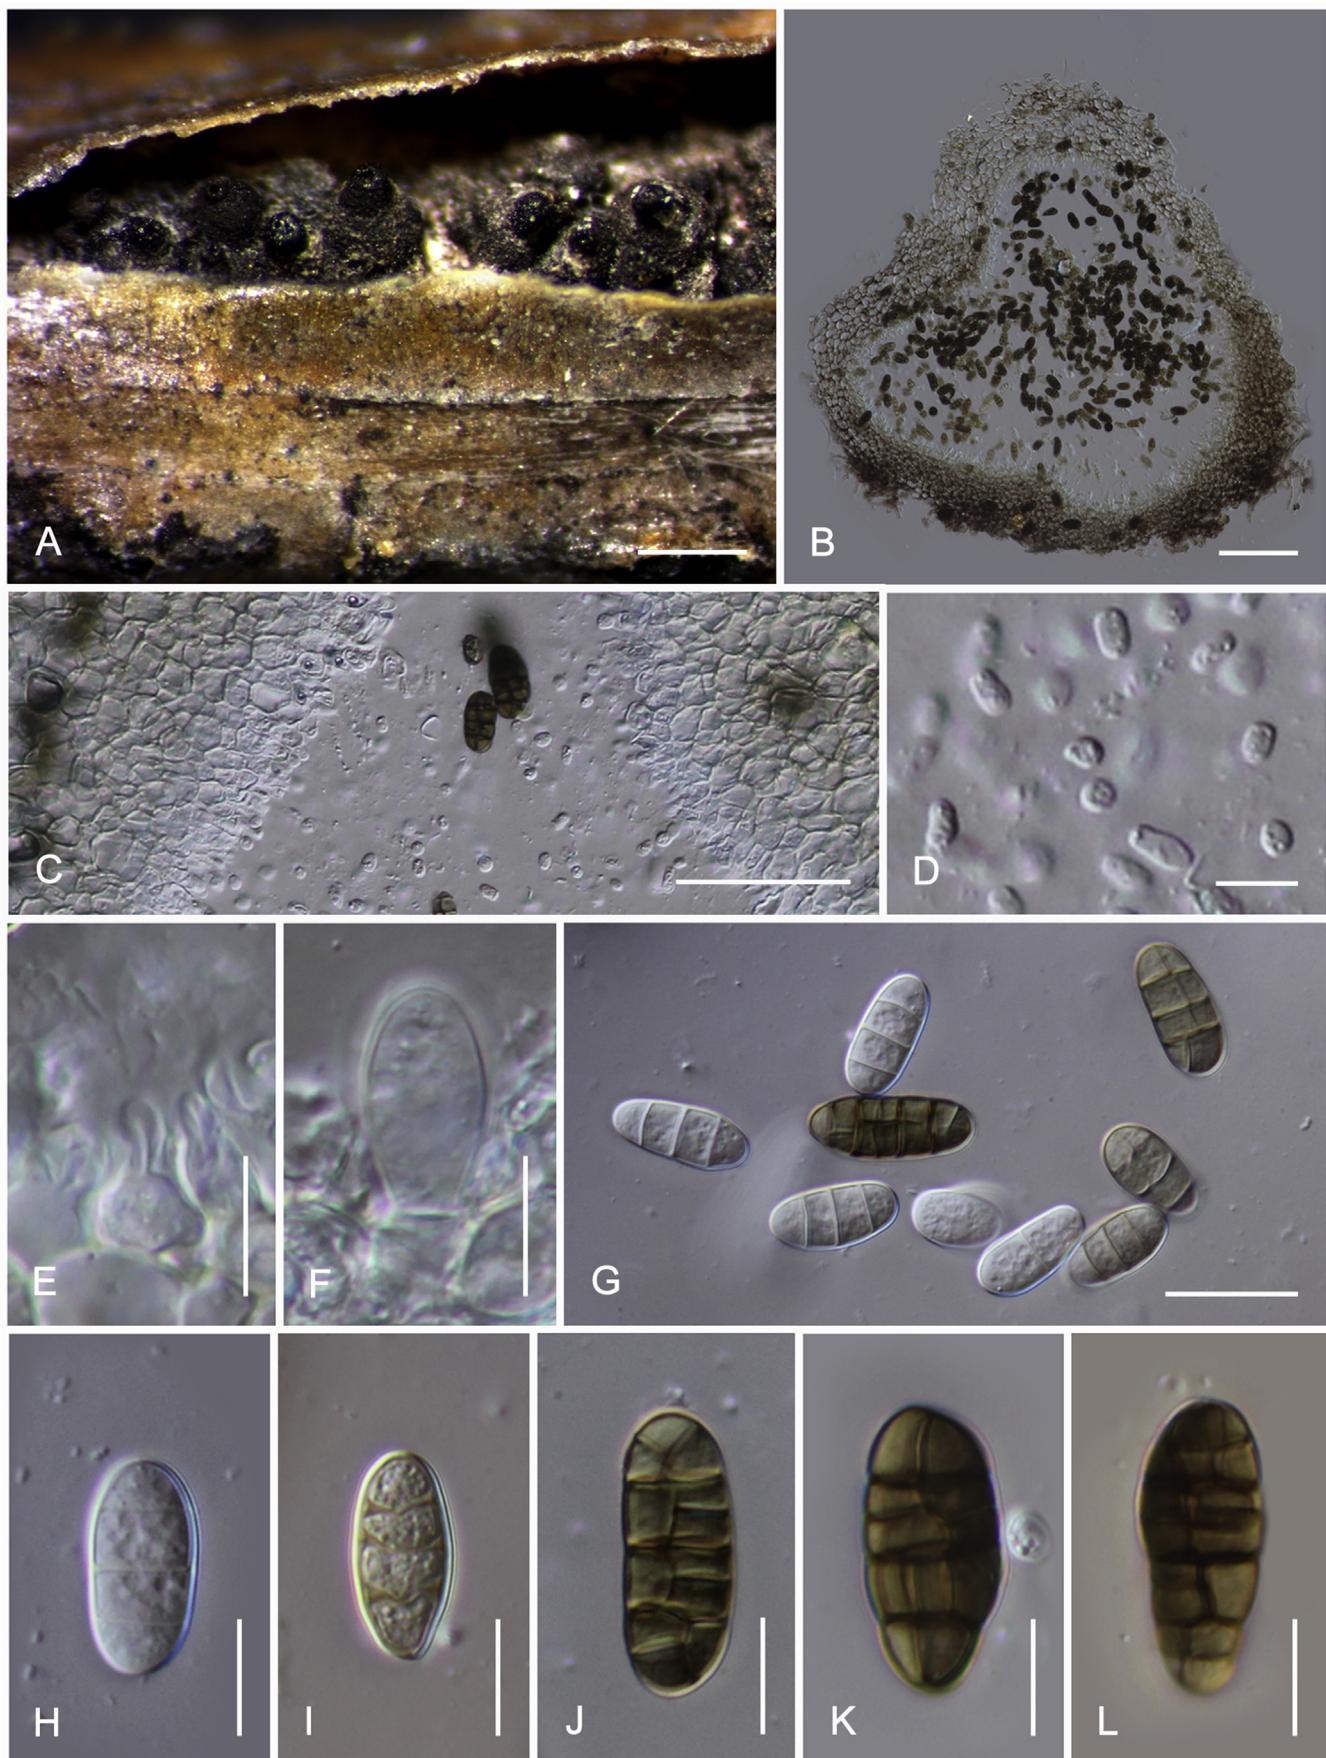

Fig. 11. *Camarosporidiella halimodendri* (MFLU 17-0463, holotype). **A.** Conidiomata on host surface. **B.** Vertical section through conidioma. **C, D.** Microconidia. **E, F.** Idiogenous cells. **G–L.** Macroconidia. Scale bars: A = 500 µm; B = 100 µm; C = 50 µm; D–F = 10 µm; G = 20 µm; H–L = 10 µm.

walled, comprising blackish to dark brown elongated cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 2–3 layers, hyaline, flattened, thin-walled cells of *textura angularis*. *Hamathecium* comprising numerous, 3.5–4.5 µm (n = 40) wide, filamentous, branched, septate, pseudoparaphyses. Asci 150–180 × 15–20 µm ($\bar{x} = 164.7 \times 18.4$ µm, n = 30), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded with a minute ocular chamber. Ascospores 30–35 × 12–14 µm ($\bar{x} = 32.9 \times 12.8$ µm, n = 50), overlapping uniseriate or sometimes overlapping biseriate, muriform, mostly ellipsoidal, 6–8-transversely septate, with 2–3 longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming brown at maturity, asymmetrical, upper part wider than lower part, slightly paler ends, conical and narrowly rounded at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 3 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin greenish grey after 6 wk, reverse greenish grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin.

Material examined: Italy, Forlì-Cesena [FC], Bagno di Romagna, Valgiana, on dead aerial twigs of *Coronilla emerus* (Fabaceae), 19 May 2013, E. Camporesi IT1283 (MFLU 16-0139, holotype, ex-type culture MFLUCC 13-0547).

Notes: *Cucurbitaria coronillae*, *Cu. elongata* and *Cu. emeri* are also recorded on *Coronilla emerus* (Munk 1957, Mirza 1968). These three species morphologically resemble *Camarosporidiella italica* with respect to their ascomata, peridium, ascii and ascospore characters. *Cucurbitaria emerus* is different from *Ca. italica* in having diplodia-like uniseptate conidia. *Cucurbitaria coronillae* differs from *Ca. italica* in having much longer ascospores (> 30 µm) with 2–3 longitudinal septa while *Cu. coronillae* has comparatively shorter ascospores (< 27 µm) with one longitudinal septum. *Cucurbitaria elongata* differs from *Ca. italica* in having a prominently thicker peridium (100–180 µm) while *Ca. italica* has a peridium up to 50 µm wide.

Camarosporidiella laburni (Pers.) Wanas., Bulgakov, Camporesi & K.D. Hyde comb. nov. MycoBank MB821952; Faceoffungi number: FoF 03540. **Figs 13, 14.**

Basionym: *Sphaeria laburni* Pers., Observ. mycol. 1: 68. 1796.

Synonyms: *Cucurbitaria laburni* (Pers.) De Not., Erb. critt. Ital., Ser. 1, fasc. 16: 875. 1862.

Gibberidea laburni (Pers.) Kuntze, Revisio generum plantarum 3: 481. 1898.

Camarosporium laburni Sacc. & Roum., Michelia 2: 630. 1882.

Saprobic on woody branches. **Asexual morph:** *Conidiomata* pycnidial, 300–350 µm high, 300–400 µm diam ($\bar{x} = 338.2 \times 326.1$ µm, n = 10), solitary to gregarious, black, immersed, unilocular, with an apapillate ostiole. *Pycnidial wall* multi-layered, 20–30 µm wide at the base, 40–50 µm wide in sides, thick, comprising 4–7 layers, outer layer heavily pigmented, thick-walled, comprising blackish to dark brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 2–3 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. *Conidia* 20–30 × 8–11 µm ($\bar{x} = 26.1 \times 9.7$ µm; n = 30), oblong, straight to slightly curved,

rounded at both ends, 4–5-transversely septate, with 1–2 longitudinal septa, muriform, smooth-walled, initially hyaline, becoming blackish brown at maturity. **Sexual morph:** *Ascomata* 400–550 µm high, 500–600 µm diam ($\bar{x} = 462.4 \times 559.9$ µm, n = 10), black, superficial to semi-immersed, confluent, gregarious, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, uniloculate, with an ostiole. *Ostiole* central, short, slightly sunken, minute and inconspicuous at the surface, smooth, ostiolar canal filled with hyaline cells. *Peridium* 40–60 µm wide at the base, 90–120 µm wide in sides, thick, comprising 10–12 layers, outermost layer heavily pigmented, thin-walled, comprising blackish to dark brown amorphous layer, middle layer heavily pigmented, thick-walled, comprising blackish to dark brown loosely packed cells of *textura angularis*, inner layer composed of 3–4 layers, reddish brown to hyaline, cells towards the inside lighter, flattened, thick-walled cells of *textura angularis*. *Hamathecium* comprising numerous, 2.5–3 µm (n = 40) wide, filamentous, branched septate, pseudoparaphyses. Asci 160–190 × 12–16 µm ($\bar{x} = 176.3 \times 14.8$ µm, n = 40), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded with a minute ocular chamber. Ascospores 27–32 × 10–12 µm ($\bar{x} = 30.4 \times 11.1$ µm, n = 50), overlapping uniseriate, muriform, mostly ellipsoidal, 6–7-transversely septate, with 1–2 longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, asymmetrical, slightly paler ends, conical and narrowly rounded at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, greenish grey after 6 wk, reverse greenish grey, flat on the surface, without aerial mycelium.

Materials examined: Italy, Forlì-Cesena, Fiumicello di Premicuore, on dead aerial branches of *Laburnum anagyroides*, 1 Jan. 2012, E. Camporesi, IT83, MFLU 16-0094, living culture MFLUCC 14-0919 = CBS 143121. Russia, Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Systematic Arboretum, 47,2360559° N, 39,6555591° E, on dead twigs of *Laburnum anagyroides* (Fabaceae), 5 Mar. 2014, T.S. Bulgakov T-003, MFLU 17-0451, living culture MFLUCC 14-0885; Rostov-on-Don city, Botanical Garden of Southern Federal University, Systematic Arboretum, 47,2350733° N, 39,6541689° E, on *Laburnum anagyroides*, 30 May 2015, T.S. Bulgakov T-838, MFLU 15-2981, living culture MFLUCC 17-0709; Republic of Crimea, Feodosia city Municipality, Tepe-Oba ridge, artificial forest, 44,0108725° N, 35,3541327° E, on dead branches of *Laburnum anagyroides*, 23 Jun. 2016, T.S. Bulgakov CR029 (MFLU 17-1434, living culture MFLUCC 17-0751 = CBS 143120) *ibid.* CR032 (MFLU 17-1435, living culture MFLUCC 17-0752)

Notes: *Camarosporidiella laburni* (= *Cucurbitaria laburni*) was introduced by De Notaris (1862) for a collection from Italy. Our collection is also from Italy, which fits with the original description of *Cm. laburni* (De Notaris 1862) and the description of Mirza (1968). A comprehensive comparison of *Cm. laburni* with other species is given by Green (1931) and Mirza (1968), which is clearly different from the remaining described species in *Cucurbitaria*. By considering the continent, host and morphological evidence, we introduce DNA-based molecular data for *Cm. laburni* as *Ca. laburni*. Furthermore, in this study the strains (MFLUCC 14-0885, 17-0704, 17-0752, 17-0709, 17-0751, from conidia) cluster together with *C. laburni* (Subclade A3, Fig. 1) and we consider them belong to this species as the asexual

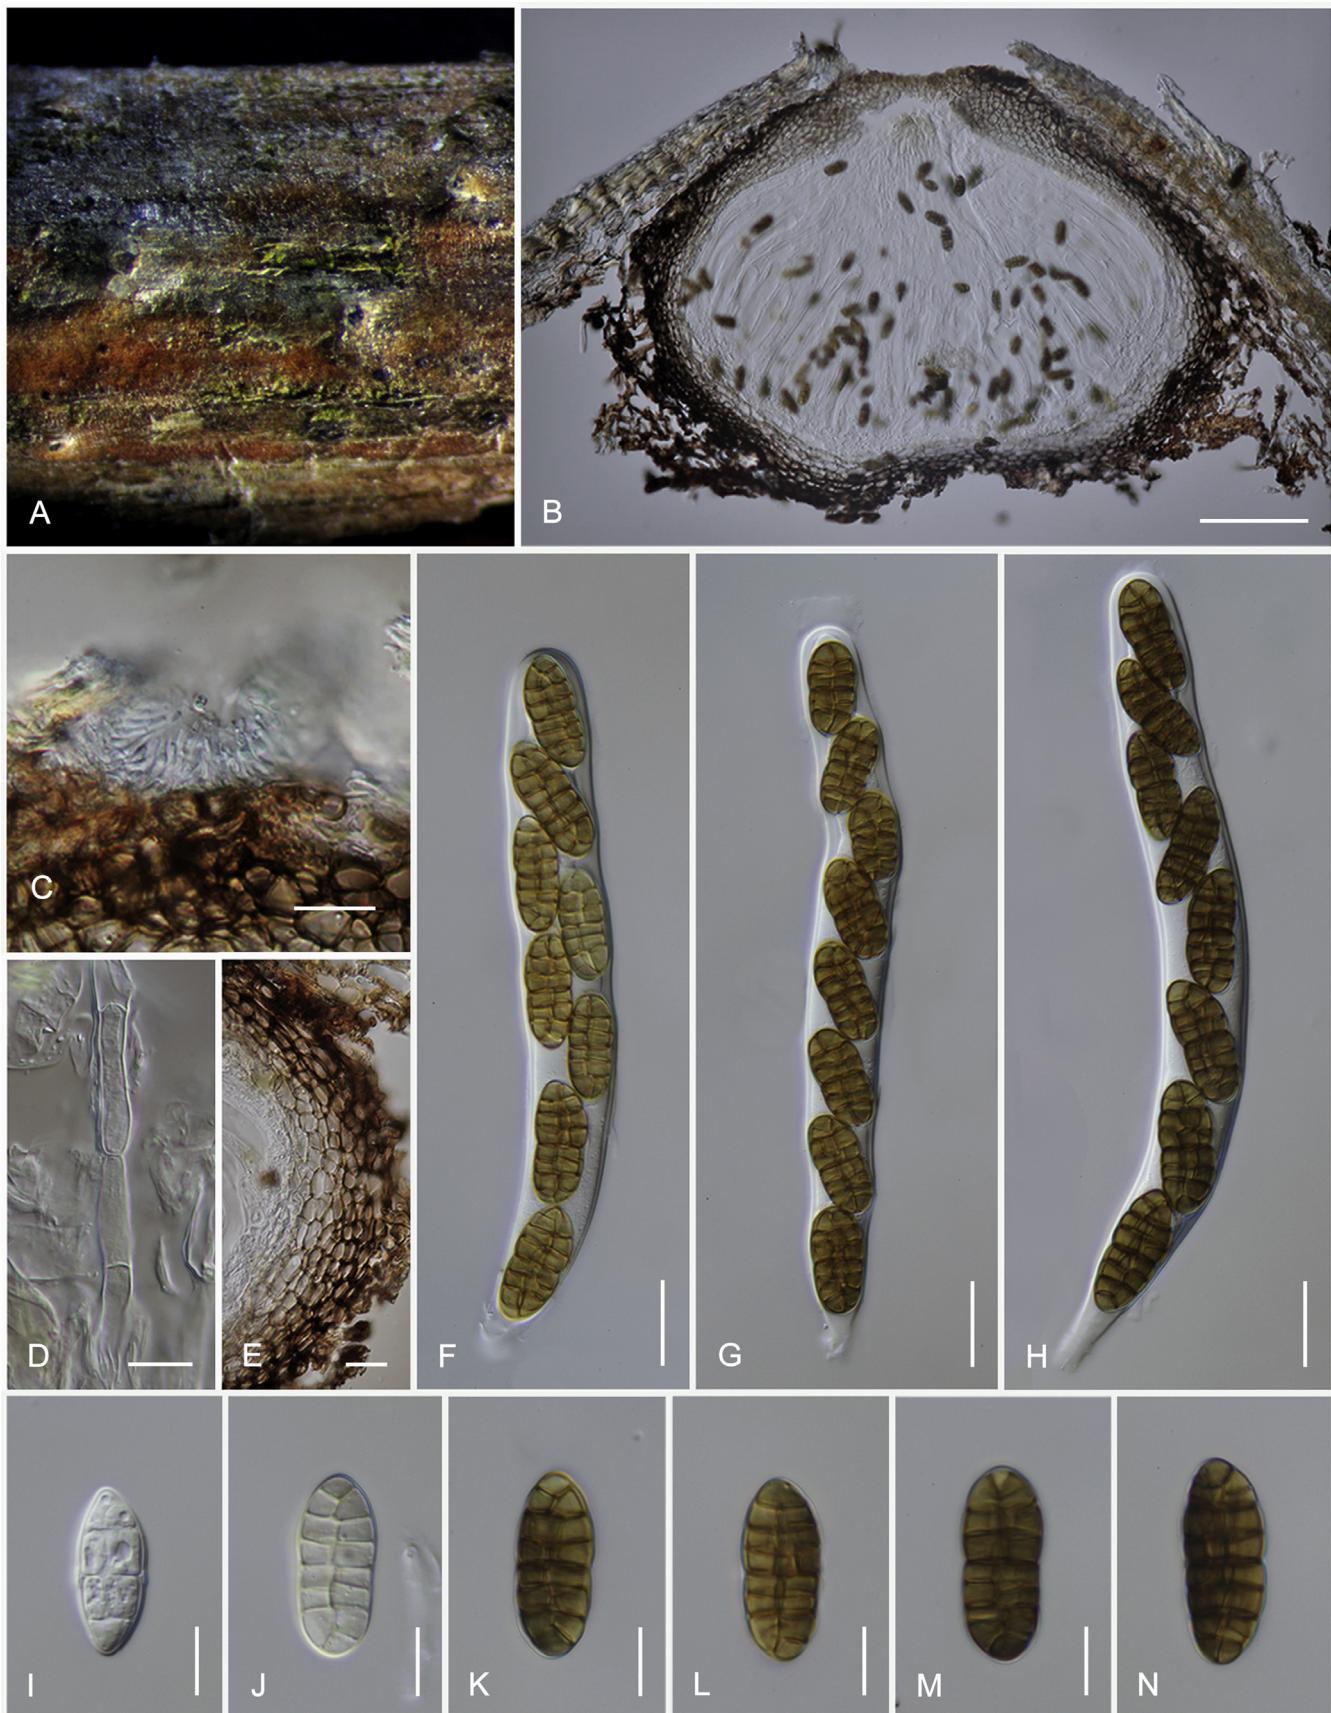

Fig. 12. *Camarosporidiella italica* (MFLU 16-0139, holotype). **A.** Appearance of ascomata on host substrate. **B.** Section of ascoma. **C.** Closeup of ostiole. **D.** Pseudoparaphyses. **E.** Peridium. **F–H.** Asci. **I–N.** Ascospores. Scale bars: B = 100 µm; C, E, F–H = 20 µm; D, I–N = 10 µm.

morph. *Camarosporidiella clematidis* clusters in a subclade sister to *Ca. laburni*, but morphologically differs from *Ca. laburni* in having smaller conidia ($10\text{--}17 \times 7\text{--}9 \mu\text{m}$) while *Ca. laburni* has comparatively larger conidia ($20\text{--}30 \times 8\text{--}11 \mu\text{m}$).

Camarosporidiella laburnicola (R.H. Perera et al.) Wanas. & K.D. Hyde, **comb. nov.** MycoBank MB821953; Facesoffungi number: FoF 03541.

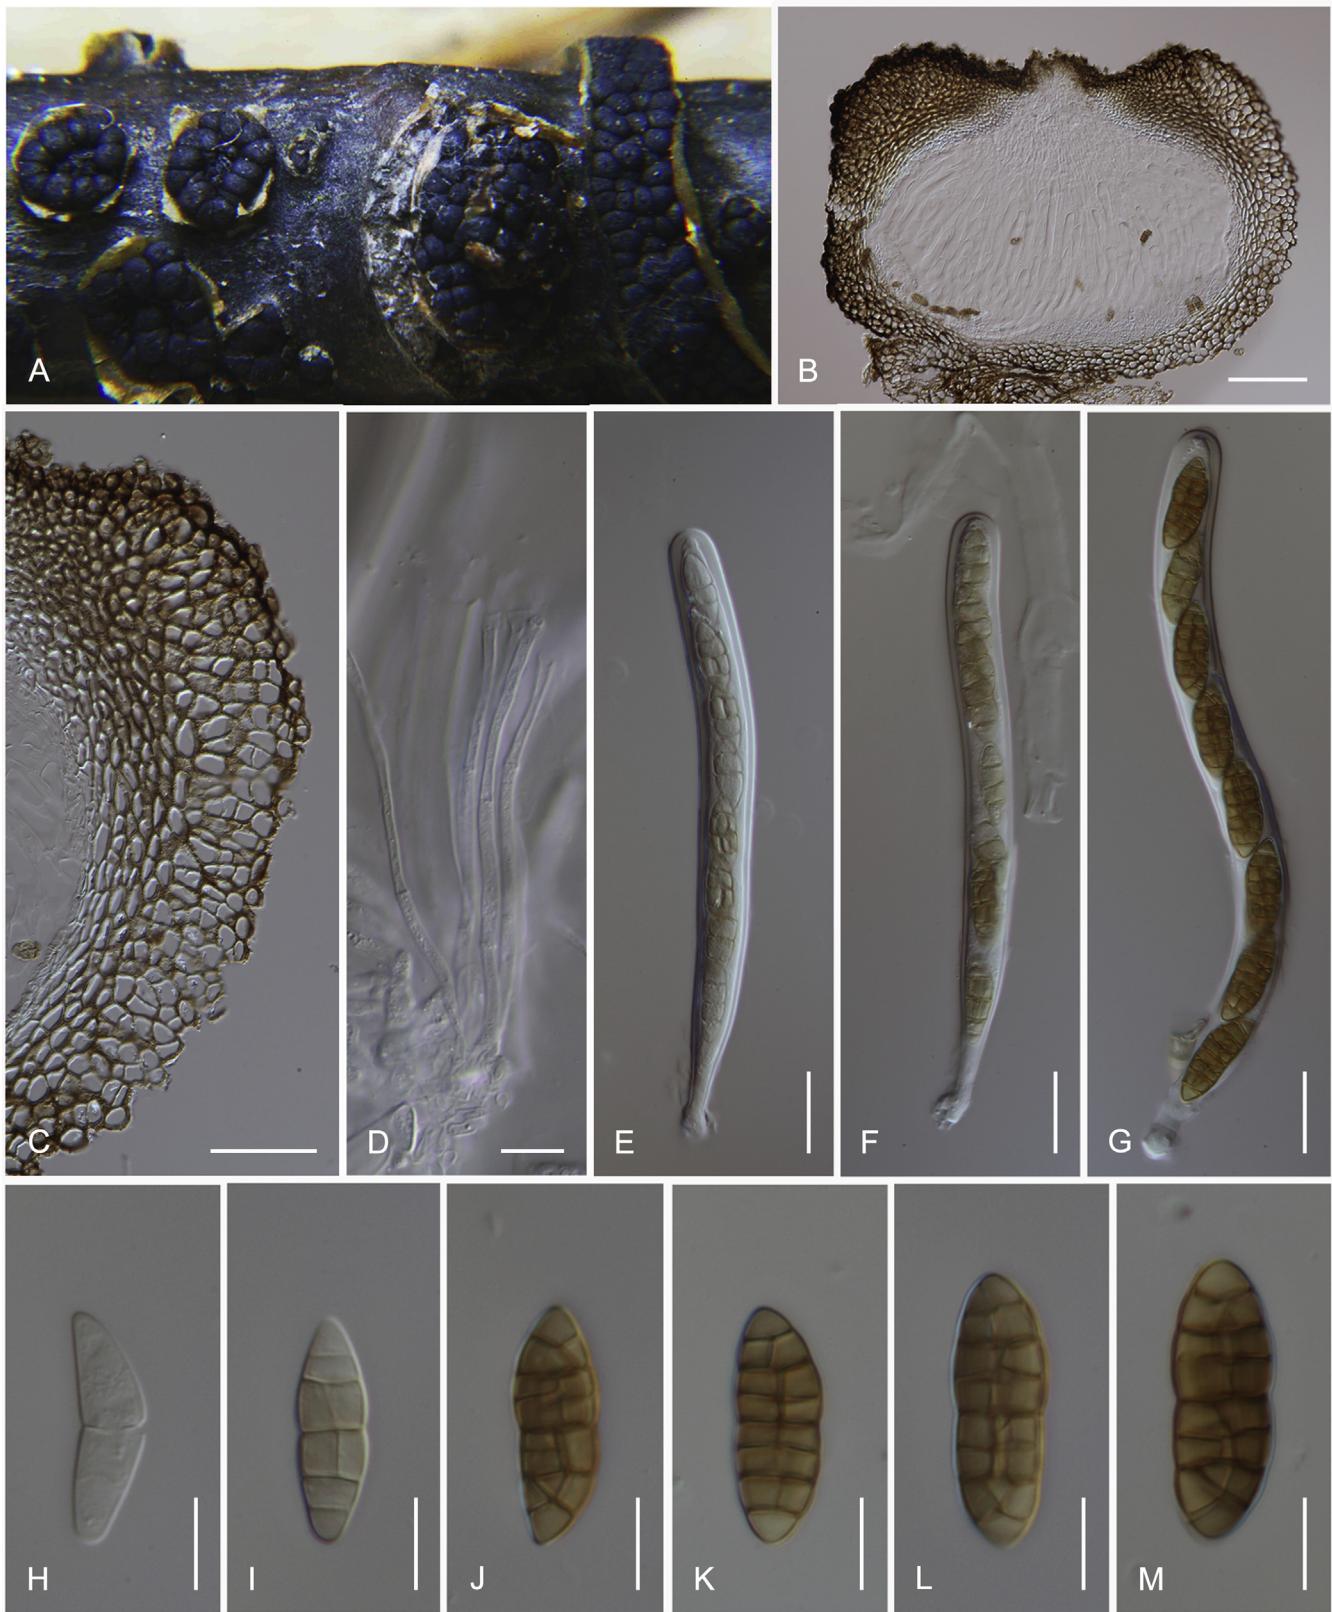

Fig. 13. Sexual morph of *Camarosporidiella laburnicola* (MFLU 16-0094). **A.** Appearance of ascocarps on host substrate. **B.** Section of ascocarp. **C.** Peridium. **D.** Pseudoparaphyses. **E–G.** Ascii. **H–M.** Ascospores. Scale bars: B = 100 µm; C = 50 µm; D, H–M = 10 µm; E–G = 20 µm.

Basionym: *Camarosporium laburnicola* R.H. Perera et al., Fungal Diversity 83: 97. 2017.

Illustrations: See [Tibpromma et al. \(2017\)](#).

Notes: *Camarosporidiella laburnicola* (Subclade A3, Fig. 1) was isolated from *Laburnum anagyroides* and is morphologically similar to *Ca. arezzoensis*, *Ca. elongatum* and *Ca. uniseriatum*.

However, *Ca. laburnicola* differs from these taxa in having smaller ascci and ascospores with different numbers of longitudinal and transverse septa (Tibpromma et al. 2017). *Camarosporidiella laburnicola* is nested in between *Ca. laburni* and *Ca. clematidis*, but this relationship is not supported (≥ 60 ML & MP and ≥ 0.95 PP, Clade A3, Fig. 1). *Camarosporidiella laburnicola* is morphologically similar to *Ca. laburni* in ascocarps, ascii and ascospore characters. However, *Camarosporidiella laburni*

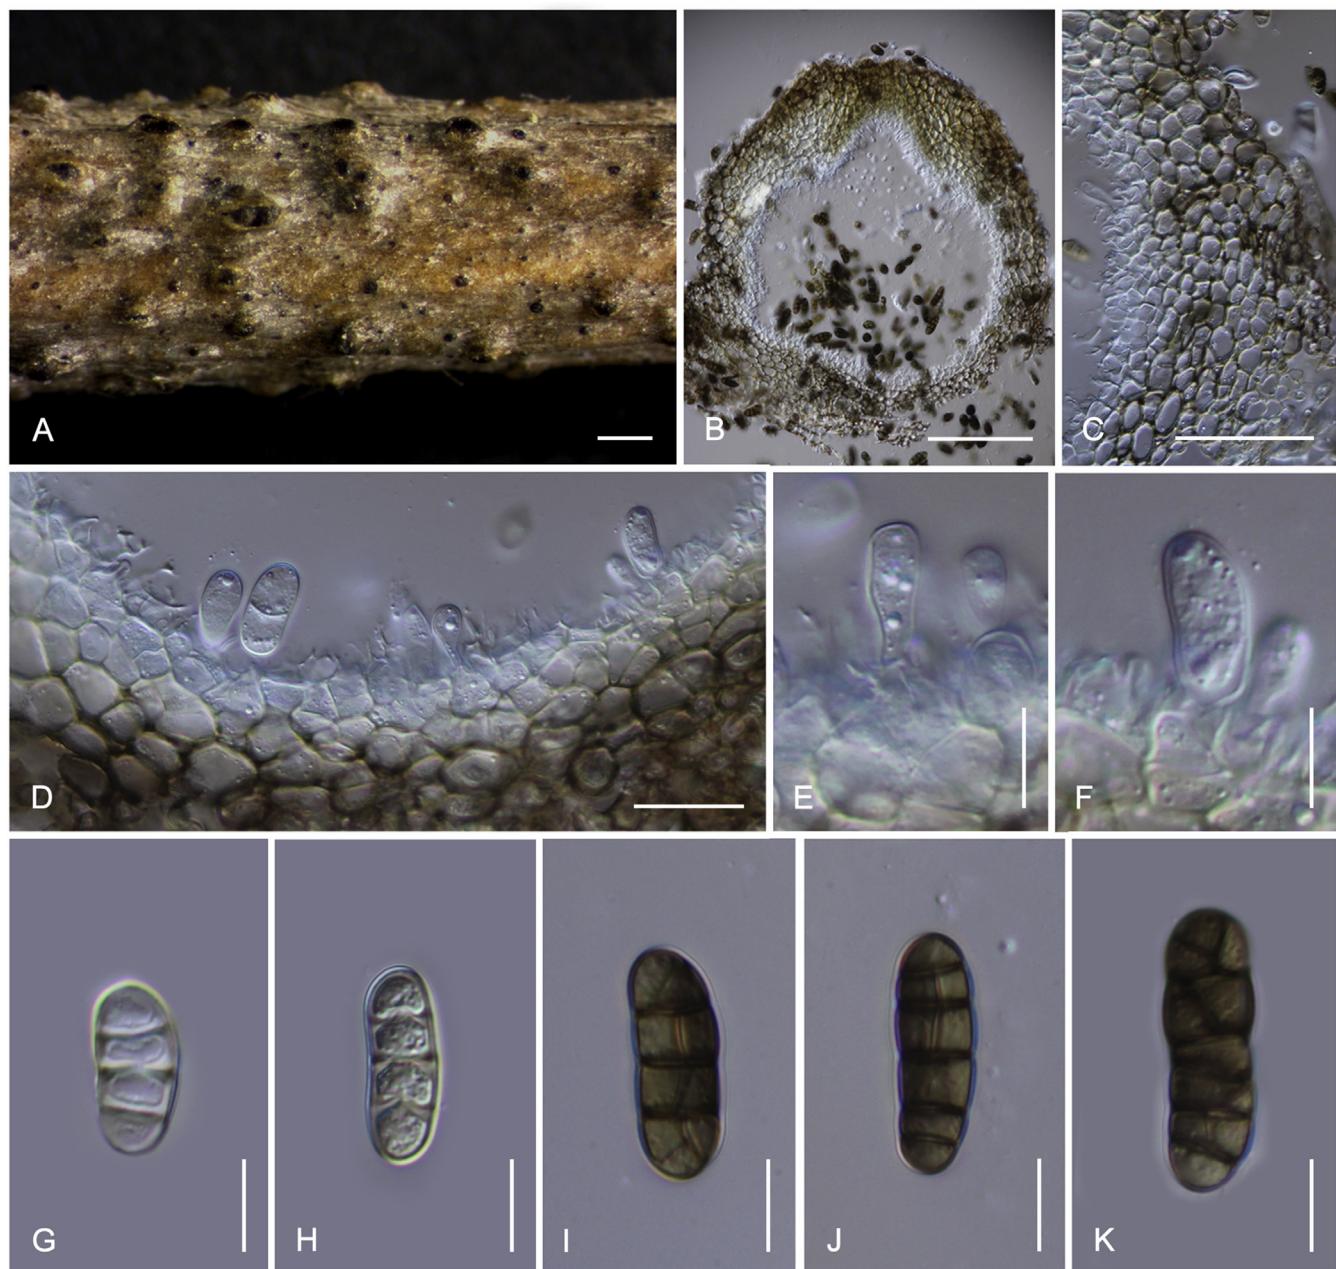

Fig. 14. Asexual morph of *Camarosporidiella laburni* (MFLU 17-0451). **A.** Conidiomata on host surface. **B.** Vertical section through conidium. **C, D.** Conidiomatal wall. **E, F.** Conidiogenous cells. **G–K.** Conidia. Scale bars: A = 500 µm; B = 100 µm; C = 50 µm; D = 20 µm; E–K = 10 µm.

differs from *Ca. laburnicola* in having much larger asci (160–190 × 12–16 µm) and ascospores (27–32 × 10–12 µm) while *Ca. laburnicola* has comparatively smaller asci (125–150 × 9–11 µm) and ascospores (15–21 × 6–8 µm).

***Camarosporidiella mackenziei* Wanas., Bulgakov & K.D. Hyde sp. nov.** MycoBank MB821954; Facesoffungi number: FoF 03542. [Fig. 15](#).

Etymology: In honour of Dr. Eric Hugh Charles Mckenzie for his immense contribution to mycology.

Necrotrophic on dying branches of *Caragana arborescens*. **Asexual morph:** *Conidiomata* pycnidial, 450–550 µm high, 500–600 µm diam ($\bar{x} = 408.4 \times 569.5$ µm, n = 10), solitary or gregarious, black, immersed to semi-eruptent, unilocular, with a papillate ostiolate. *Ostiole* 120–160 µm long, 80–90 µm diam

($\bar{x} = 140.1 \times 66.7$ µm, n = 10), central, long, smooth, sometimes ostiolar canal filled with hyaline or pale brown cells. *Pycnidial wall* multi-layered, 40–50 µm wide at the base, 40–55 µm wide in sides, thick, comprising 4–6 layers, outer layer heavily pigmented, thick-walled, comprising blackish to dark reddish-brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 1–2 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Macroconidiogenous cells* enteroblastic, annellidic, doliiform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. *Macroconidia* 17–25 × 9–13 µm ($\bar{x} = 19.6 \times 11.1$ µm; n = 50), oblong, straight to slightly curved, rounded at both ends, sometimes narrowly rounded ends, 3–4-transversely septate, with 1–2 longitudinal septa, muriform, smooth-walled, brown to dark brown. *Microconidiogenous cells* intermingled with macroconidiogenous cells, hyaline, integrated, enteroblastic with percurrent annellidic, ampulliform to

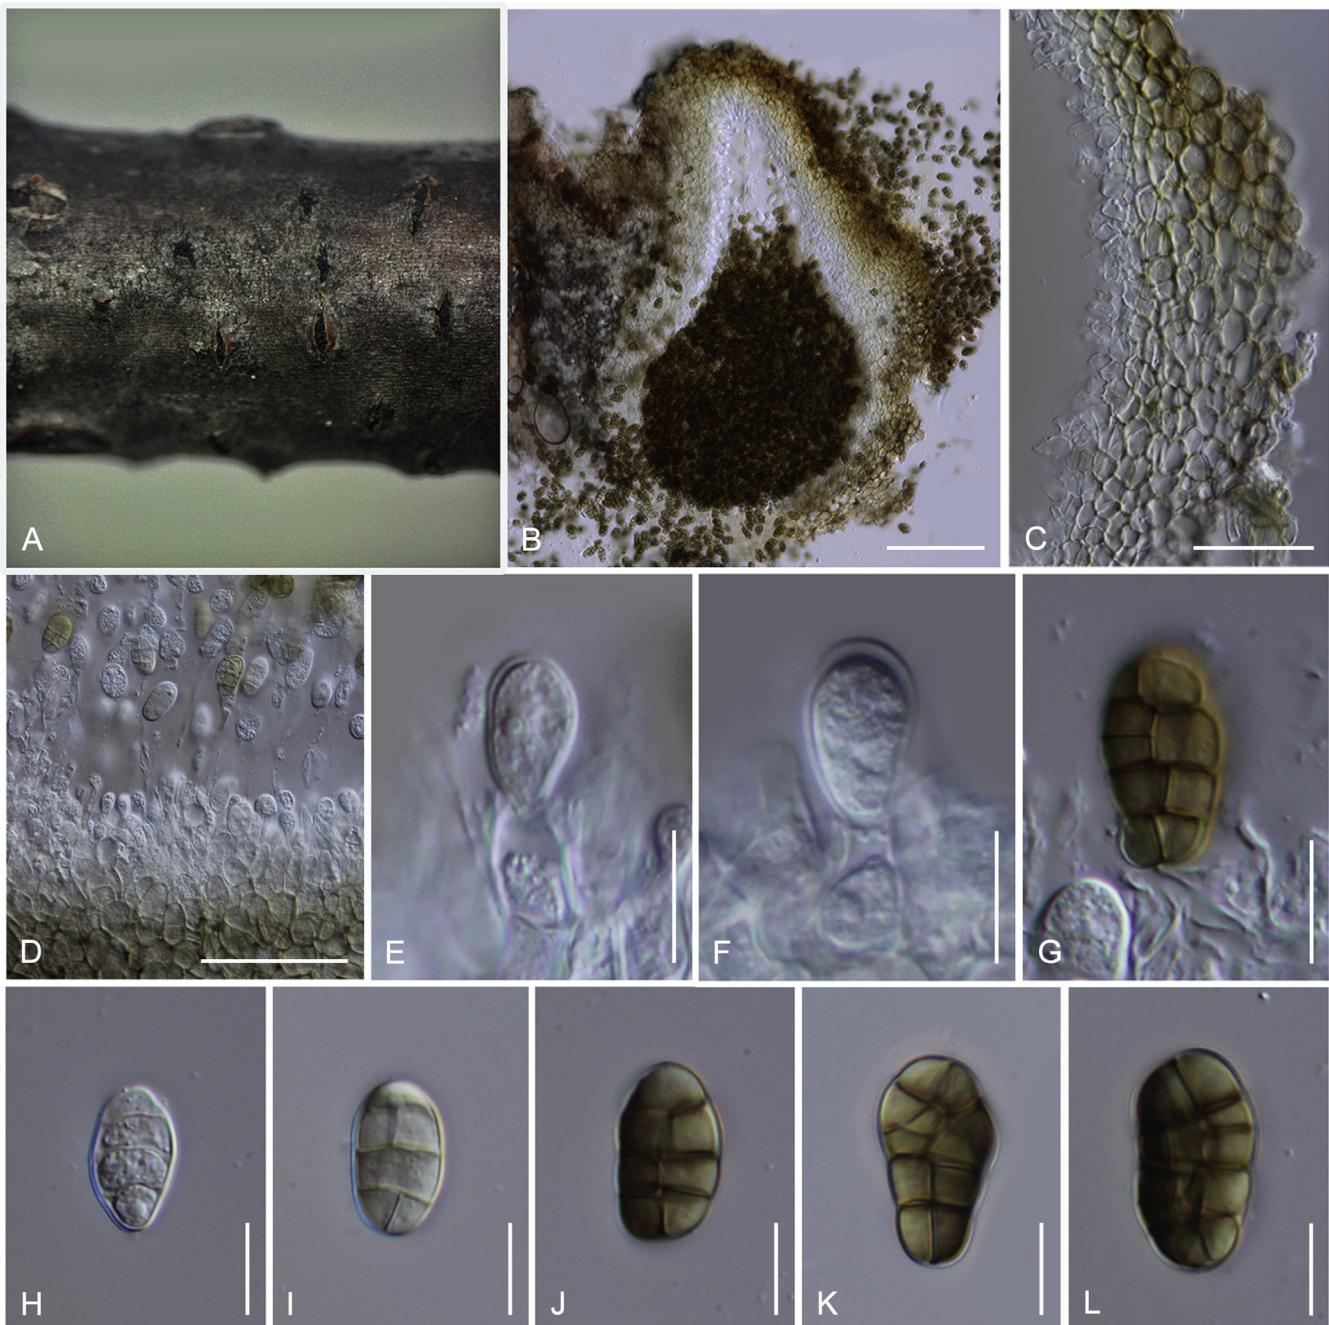

Fig. 15. *Camarosporidiella mackenziei* (MFLU 17-0449, holotype). **A.** Conidiomata on host surface. **B.** Vertical section through conidioma. **C.** Conidiomatal wall. **D.** Microconidia. **E–G.** Conidiogenous cells forming conidia. **H–L.** Macro conidia. Scale bars: B = 100 µm; C, D = 50 µm; E–L = 10 µm.

subcylindrical. *Microconidia* 6.5–8 × 4–6 µm ($\bar{x} = 7.6 \times 4.5$ µm; n = 20), hyaline, round to oblong or ellipsoidal, with small guttules. *Sexual morph:* Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, greenish grey, reverse greenish grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: **Russia**, Rostov Region, Oktyabrsky district, natural sanctuary (Persianovskaya preserved steppe), shelterbelt artificial forest, 47,5036056° N, 40,1545572° E, on dying twigs and shrubs of *Caragana arborescens* (Fabaceae), 26 Apr. 2014, T.S. Bulgakov T-001 (MFLU 17-0449, **holotype**, ex-type culture, MFLUCC 14-0883 = CBS 143123); *ibid.* T-011 (MFLU 17-0457, **paratype**, ex-paratype culture, MFLUCC 14-0893 = CBS 143124). *ibid.* 47,2350724° N, 39,6541643° E, 28 May 2015, T-810, MFLU 15-2953, **paratype**, ex-paratype living culture MFLUCC 17-0703.

Notes: *Camarosporidiella caraganicola* has also been collected from *Caragana* spp. and resembles *Ca. mackenziei* in conidial dimensions (13–26 × 6–13 µm; Liu et al. 2015) and shape. However, they are phylogenetically apart (Subclades A7 and A12 respectively, Fig. 1).

The affiliation of *Ca. mackenziei* with *Camarosporidiella* sp. (CPC 25960, CPC 25962) cannot be compared as no details are available for these isolations (Subclade A12, Fig. 1). All the three strains of *C. mackenziei* in Subclade A12 (Fig. 1) are from the same locality and host. There are slight differences in their DNA sequence data and there could be a probability that they constitute a species complex. Perhaps more collections from different regionshosts can further clarify their taxonomy in future studies. We reiterate, however, that morphologically they are similar and hence we consider them as one species.

Camarosporidiella melnikii Wanas., Bulgakov & K.D. Hyde, sp. nov. MycoBank MB821955; Facesoffungi number: FoF 03543. **Fig. 16.**

Etymology: In honour of Vadim Alexandrovich Mel'nik (March 16, 1937 – April 10, 2017) for his immense contribution to mycology.

Necrotrophic on dying branches of *Caragana frutex*. **Asexual morph:** *Conidiomata* pycnidial, 350–550 µm high, 300–500 µm diam ($\bar{x} = 457.7 \times 393.1$ µm, n = 10), black, superficial to semi-immersed, confluent, gregarious, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, ostiolate. *Ostiole* central, short, slightly sunken, minute, inconspicuous on surface, smooth, with ostiolar canal filled with hyaline cells. *Ostiole* 120–180 µm long, 70–90 µm diam ($\bar{x} = 150.1 \times 82.7$ µm, n = 10), central, long, smooth, sometimes ostiolar canal filled with hyaline or pale brown cells. *Pycnidial wall* multi-layered, 40–50 µm wide at the base, 40–75 µm wide in sides, thick, comprising 4–8 layers, outer layer heavily pigmented, thick-walled, comprising blackish to dark reddish-brown cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 2–4 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Macroconidiogenous cells* enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. *Macroconidia* 11–16 × 5–6 µm ($\bar{x} = 13.3 \times 5.5$ µm; n = 50), oblong, straight, rounded at both ends, sometimes narrowly rounded ends, 2–3-transversely septate, without longitudinal septa, smooth-walled, initially hyaline, becoming brown to dark brown at maturity. *Microconidiogenous cells* intermingled with macroconidiogenous cells, hyaline, integrated, enteroblastic with percurrent annellidic, ampulliform to subcylindrical. *Microconidia* 7–12 × 4–7 µm ($\bar{x} = 9.6 \times$ µm; n = 20), hyaline, round to oblong or ellipsoidal, with small guttules. **Sexual morph:** Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin dirty white after 6 wk, reverse creamy, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Material examined: Russia, Rostov region, Shakhty city, Cotton Fabric urban microdistrict, Grushevka steppe slopes near Grushevsky Pond, 47, 7234186° N, 40, 255065° E, on dead aerial branches of *Caragana frutex* (Fabaceae), 12 May 2015, T.S. Bulgakov T-318, MFLU 15-2022, **holotype**, ex-type living culture MFLUCC 17-0684.

Notes: *Camarosporidiella melnikii* is an independent taxon (sister to *Ca. caraganicola* isolates) and segregates from others with high statistical support (Subclade A7, **Fig. 1**). *Ca. melnikii* has smaller conidia (11–16 × 5–6 µm) without longitudinal septa, while *Camarosporidiella caraganicola* has comparatively larger conidia (13–26 × 6–13 µm; Liu et al. 2015) with longitudinal septa. *Camarosporidiella melnikii* also resembles *Ca. celtidis* in having 2–3-transversely septate conidia, without longitudinal septa, but phylogeny herein supports their distinction (Subclades A7 and A5 respectively, **Fig. 1**).

Camarosporidiella mirabellensis Wanas., Camporesi & K.D. Hyde, sp. nov. MycoBank MB821956; Facesoffungi number: FoF 03544. **Fig. 17.**

Etymology: *mirabellensis*, due to its occurrence in Monte Mirabello, Italy.

Saprobic on woody branches. **Asexual morph:** Undetermined. **Sexual morph:** *Ascomata* 300–350 µm high, 500–550 µm diam ($\bar{x} = 323.9 \times 523.3$ µm, n = 10), black, immersed to semi-erumpent, solitary or gregarious, broadly oblong, cupulate when dry. *Peridium* 50–80 µm wide at the base, 60–90 µm wide in sides, thick, comprising 8–10 layers, outer layer heavily pigmented, thick-walled, comprising blackish to dark brown elongated cells of *textura angularis*, cells towards the inside lighter, inner layer composed of 2–3 layers, hyaline, flattened, thin-walled cells of *textura angularis*. *Hamathecium* comprising numerous, 1.5–2 µm (n = 30) wide, filamentous, branched, septate, pseudoparaphyses. *Asci* 140–170 × 12–16 µm ($\bar{x} = 158.8 \times 13.7$ µm, n = 30), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded with a minute ocular chamber. *Ascospores* 22–27 × 9–11 µm ($\bar{x} = 24.8 \times 9.9$ µm, n = 40), overlapping uniseriate or sometimes overlapping biseriate, muriform, mostly ellipsoidal, 3–5-transversely septate, with 1–2 longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming brown at maturity, asymmetrical, slightly paler ends, conical and narrowed at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 3 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin dirty white after 6 wk, reverse creamy, flat on the surface, without aerial mycelium.

Material examined: Italy, Forli-Cesena [FC], Predappio, Monte Mirabello, on dead aerial branches of *Robinia pseudoacacia* (Fabaceae), 3 Oct. 2014, E. Camporesi IT 2139 (MFLU 16-0228, **holotype**).

Notes: Unfortunately, we could not manage to maintain a living culture as subsequent attempts to subculture failed, and hence a living culture is unavailable. *Camarosporidiella elongata* and *Ca. spartii* have also been reported on *Robinia pseudoacacia* and morphologically resemble our new collection of *Ca. mirabellensis* in their ascocarps, peridium, ascus and ascospore characteristics (Mirza 1968). However, *Ca. mirabellensis* differs from *Ca. elongata* and *Ca. spartii* in having ascospores with fewer transverse septa (< 5). In multi-gene phylogenetic analyses, *Ca. mirabellensis*, *Ca. eufemiana* and *Ca. premilcurensis* are more closely related (Subclade A4, **Fig. 1**). We must point out that despite not having sufficient phylogenetic differences, we consider them morphologically different in terms of spore shape, structure and septation. While *Ca. mirabellensis* has pointed ends and more than one longitudinal septum, *Ca. eufemiana* has much more rounded ends with one longitudinal septum. *Camarosporidiella premilcurensis*, on the other hand, has larger ascus, and more transverse septa. Therefore, we introduce *Ca. mirabellensis* as a novel species in order to minimize taxonomic ambiguity of *Camarosporidiella*.

Camarosporidiella moricola (Chethana et al.) Wanas. & K.D. Hyde, comb. nov. MycoBank MB821957; Facesoffungi number: FoF 03545.

Basionym: *Camarosporium moricola* Chethana et al., Fungal Diversity 83: 101. 2017.

Illustrations: See Tibpromma et al. (2017).

Notes: Tibpromma et al. (2017) introduced *Camarosporidiella moricola* (= *Camarosporium moricola*) with three isolates, which were collected from *Morus alba* in Russia. In this study, we add another 12 strains to *Camarosporidiella moricola* (Subclade A1, Fig. 1) which were also collected from *Morus alba* in Russia. See more details in Tibpromma et al. (2017).

Camarosporidiella premilcurensis Wanas., Camporesi & K.D. Hyde, sp. nov. MycoBank MB821958; Facesoffungi number: FoF 03546. Fig. 18.

Etymology: *premilcurensis*, due to its occurrence in Premilcuore, Italy.

Saprobic on *Cytisus* sp. Asexual morph: Undetermined. Sexual morph: Ascomata 400–450 µm high, 500–600 µm diam ($\bar{x} = 442.1 \times 531.7$ µm, n = 10), black, superficial to semi-immersed, confluent, gregarious, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, uniloculate, with an apapillate ostiole. Ostiole central, short, slightly sunken, minute and inconspicuous at the surface, smooth, ostiolar canal filled with hyaline cells. Peridium 30–50 µm wide at the base, 60–90 µm wide in sides, thick, comprising 8–15 layers, outermost layer heavily pigmented, thin-walled, comprising blackish to dark brown amorphous layer, middle layer heavily pigmented, thick-walled, comprising blackish to dark brown loosely packed cells of *textura angularis*, inner layer composed of 3–4 layers, reddish brown to hyaline, cells towards the inside lighter, flattened, thick-walled cells of *textura angularis*. Hamathecium comprising numerous, 2.5–3.5 µm (n = 40) wide, filamentous, branched septate, pseudoparaphyses. Ascii 160–210 × 14–16 µm ($\bar{x} = 181.1 \times 15$ µm, n = 40), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded with a minute ocular chamber. Ascospores 22–27 × 10–12 µm ($\bar{x} = 24.7 \times 10.9$ µm, n = 50), overlapping uniseriate, muriform, mostly ellipsoidal, 5–7-transversely septate, with 1–2 longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, asymmetrical, slightly paler, conical and narrowly rounded at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, creamy after 6 wk, reverse greenish grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Material examined: Italy, Forli-Cesena [FC], Premilcuore, Fantella, on dead aerial twigs of *Cytisus* sp. (Fabaceae), 28 Jan. 2014, E. Camporesi, IT1681 (MFLU 16-0185, holotype, ex-type culture MFLUCC 14-0939 = CBS 143127).

Notes: *Camarosporidiella laburni* has also been collected from the same host genus, *Cytisus* (Farr & Rossman 2017) and morphologically resembles *Ca. premilcurensis* in having similar ascomata, peridium, ascii and ascospore characters. However, *Ca. laburni* has longer ascospores (> 27 µm) and a thicker peridium (> 100 µm), while *Ca. premilcurensis* has comparatively shorter ascospores (< 27 µm) and thinner peridium (> 90 µm). *Camarosporidiella premilcurensis* (Subclade A4, Fig. 1) is also phylogenetically distant from *Ca. laburni* and the latter appears to be more closely related to *Ca. laburnicola* and *Ca. clematidis* (Subclade A3, Fig. 1).

Camarosporidiella robiniicola (Wijyaw. et al.) Wijyaw., Wanas. & K.D. Hyde, comb. nov. MycoBank MB821959; Facesoffungi number: FoF 03547.

Basionym: *Camarosporium robiniicola* Wijyaw. et al., Phytotaxa 183: 21. 2014.

Synonym: *Camarosporium aureum* Norphanphoun et al., Fungal Diversity 72: 153. 2015.

Illustrations: See Wijyawawardane et al. (2014a) and Liu et al. (2015).

Additional material examined: Russia, Rostov Region, Krasnosulinsky District, Donskoye forestry, artificial forest, 47,8621251° N, 40,2313757° E, on dead twigs of *Gleditsia triacanthos* (Fabaceae), 21 May 2013, T.S. Bulgakov T-042, MFLU 17-0468, living culture MFLUCC 14-0906 = CBS 143130; Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Higher Park, 47, 2352837° N, 39, 6490788° E, on dead twigs of *Gleditsia triacanthos*, 14 May 2013, T.S. Bulgakov T-010, MFLU 17-0456, living culture MFLUCC 14-0892 = CBS 143128; Rostov region, Shakhty city, Atyukhta river valley, railroad artificial forest, 47,7113209° N, 40,1831603° E, on *Robinia neomexicana* (Fabaceae), 14 Mar. 2014, T.S. Bulgakov T-012, MFLU 17-0458, living culture MFLUCC 14-0894 = CBS 143129; Rostov-on-Don city, Botanical garden of Southern Federal University, Higher Park, 47,2389405° N, 39,6484137° E, on *Robinia pseudoacacia* (Fabaceae), 8 May 2014, T.S. Bulgakov T-053, MFLU 17-0471, living culture MFLUCC 14-0909 = CBS 143131; Shakhty city, 20th anniversary of Red Army microdistrict, Solyonaya Balka, 47,7104113° N, 340,2627254° E, on *Robinia pseudoacacia*, 21 May 2015, T.S. Bulgakov T-403, MFLU 15-2104, living culture MFLUCC 17-0688; ibid., on *Robinia* sp., 21 May 2016, T.S. Bulgakov T-1303, MFLU 16-1597, living culture MFLUCC 17-0688 = CBS 143132; ibid., on *Robinia* sp., 5 Jun. 2016, T.S. Bulgakov DL004, MFLU 16-2300, living culture MFLUCC 17-0733.

Notes: All strains of *Camarosporidiella robiniicola* (including the strain of *Ca. aureum*, MFLUCC 14-0620) cluster together with significant statistical support of 97 % for ML, 88 % for MP and 1.00 for PP (Clade A2, Fig. 1). Morphological comparison reveals identical morphs and our phylogeny strongly supports an association of *Ca. aureum* with other strains of *Ca. robiniicola*. Therefore, it would be taxonomically correct to treat them as conspecific. We herein synonymise *Camarosporium aureum* under *Ca. robiniicola*. See Liu et al. (2015) for more details on *Camarosporium aureum*.

Camarosporidiella schulzeri Wanas., Bulgakov & K.D. Hyde, sp. nov. MycoBank MB821960; Facesoffungi number: FoF 03548. Fig. 19.

Etymology: Named after Stephan V.M. Schulzer, who introduced the genus *Camarosporium*.

Necrotrophic on dying branches of *Elaeagnus angustifolia*. Asexual morph: Conidiomata pycnidial, 370–420 µm high, 380–460 µm diam ($\bar{x} = 366.4 \times 420.7$ µm, n = 10), solitary or gregarious, black, immersed or partly erumpent, unilocular, ostiolate. Ostiole 50–80 µm long, 50–70 µm diam ($\bar{x} = 67.2 \times 60.4$ µm, n = 6), central, long, smooth, sometimes ostiolar canal filled with hyaline or pale brown cells. Pycnidial wall multi-layered, 15–25 µm wide at the base, 25–35 µm wide in sides, thick, comprising 4–5 layers, with heavily pigmented outer layer, thick-walled, comprising blackish to dark reddish-brown cells of *textura angularis*, with lighter cells towards the inside, with inner layer composed of 1–2 layers, hyaline, thin-walled cells of *textura angularis*. Conidiophores reduced to conidiogenous cells. Macroconidiogenous cells enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. Macroconidia 15–21 × 8–12 µm ($\bar{x} = 18.9 \times 10.1$ µm; n = 40), oblong, straight to slightly curved, rounded at both ends, 2–3-transversely septate, with one longitudinal septum, muriform, smooth-walled, brown to dark brown. Microconidiogenous cells intermingled with macroconidiogenous cells, hyaline, integrated,

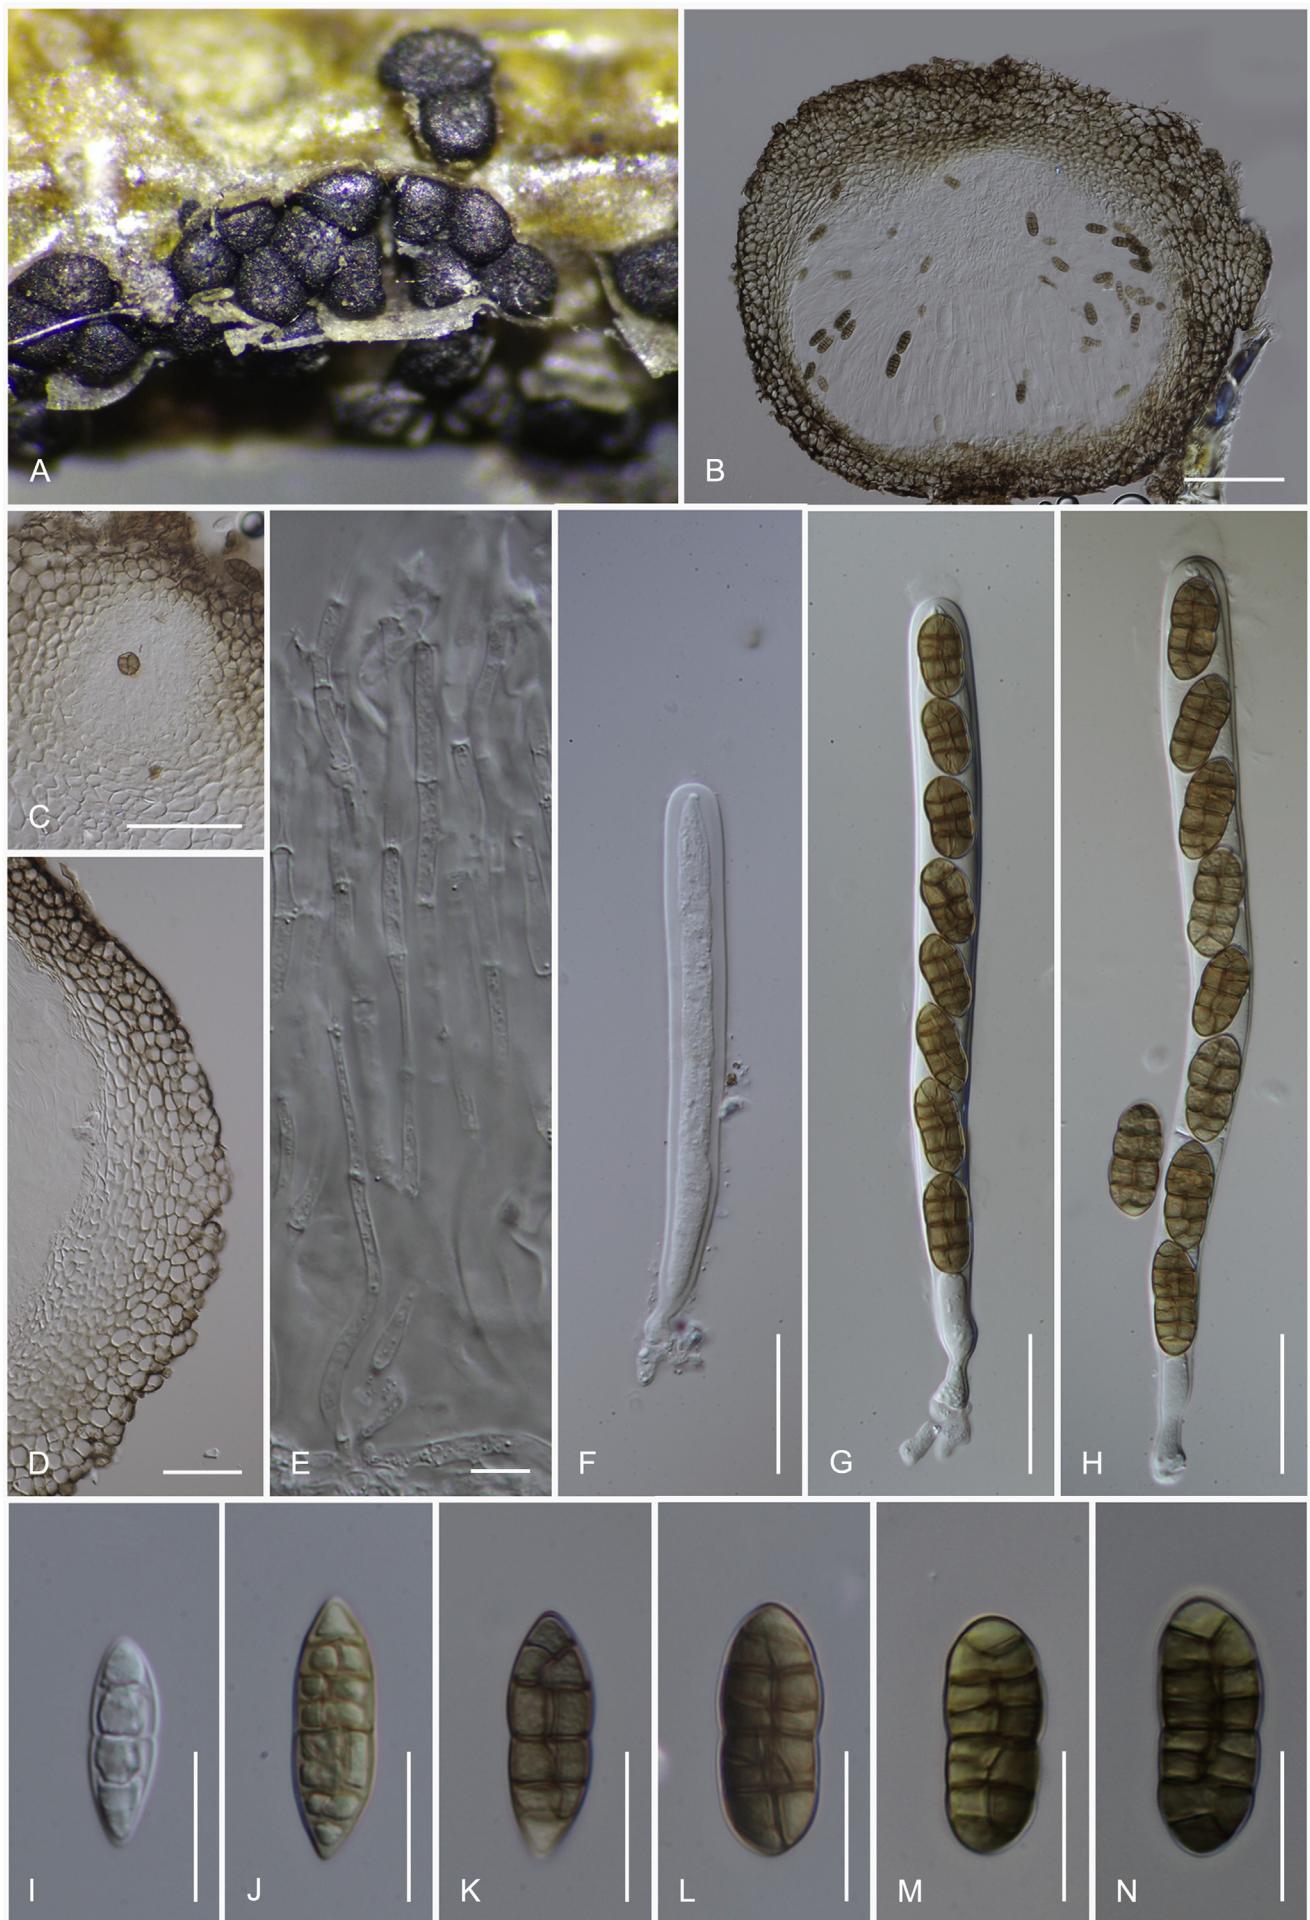

Fig. 18. *Camarosporidiella premilcurensis* (MFLU 16-0185, holotype). **A.** Appearance of ascocarps on host substrate. **B.** Section of ascoma. **C.** Close-up of ostiole. **D.** Peridium. **E.** Pseudoparaphyses. **F–H.** Ascii. **I–N.** Ascospores. Scale bars: B = 100 µm; C, D = 50 µm; E = 5 µm; F–H = 20 µm; I–N = 10 µm.

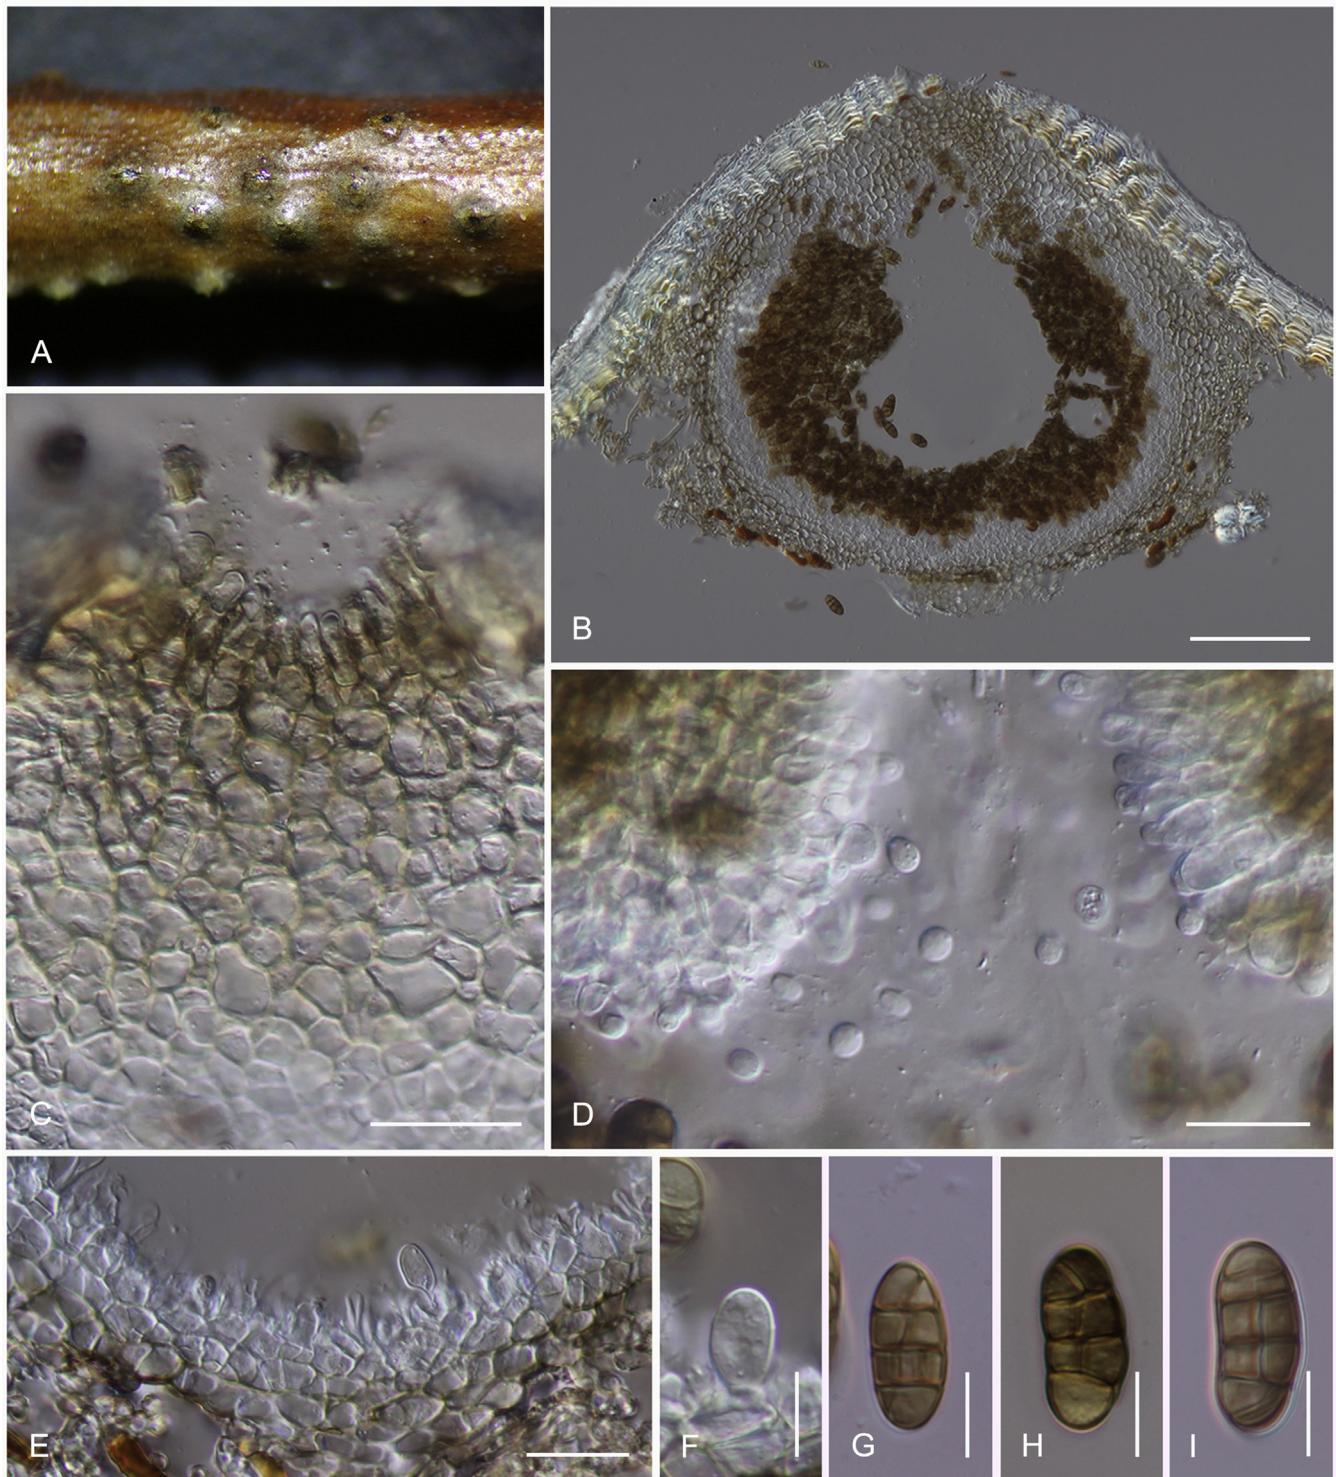

Fig. 19. *Camarosporidiella schulzeri* (MFLU 17-0460, holotype). **A.** Conidiomata on host surface. **B.** Vertical section through conidioma. **C.** Close-up of ostiole. **D.** Microconidia. **E.** Conidiogenous cells. **F–I.** Conidia. Scale bars: **B** = 100 µm; **C** = 50 µm; **D**, **E** = 20 µm; **F–I** = 10 µm.

enteroblastic, annellidic, ampulliform to subcylindrical. *Microconidia* 4.5–6.5 × 4.5–5.5 µm ($\bar{x} = 5.9 \times 4.9$ µm; $n = 25$), hyaline, round to oblong or ellipsoidal, with a few small guttules. *Sexual morph:* Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, white, reverse cream-grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: Russia, Rostov Region, Rostov-on-Don city, Botanical garden of Southern Federal University, Higher Park, underwood, 47°23'60.559" N, 39°65'55.91" E, on *Elaeagnus angustifolia* (Fabaceae), 26 Mar. 2014, T.S. Bulgakov

T-014 (MFLU 17-0460, **holotype**, ex-type culture, MFLUCC 14-0897 = CBS 143133); Oktyabrsky district, south of Persianovsky settlement, Balka Khoruli (Khoruli gully), 47°50'36.926" N, 40°12'41.732" E, on *Gleditsia triacanthos*, 28 Apr. 2015, T.S. Bulgakov T-205, MFLU 15-1909; *ibid.*, on *Robinia* sp., 14 Mar. 2016, T.S. Bulgakov T-1305, MFLU 16-1599, living culture MFLUCC 17-0722; *ibid.*, on *Robinia* sp., 24 Mar. 2016, T.S. Bulgakov T-1370, MFLU 16-1664, living culture MFLUCC 17-0722.

Notes: The holotype of *Camarosporidiella schulzeri* was collected from *Elaeagnus angustifolia*, and *Camarosporium caraganae* (conidia 14–22 × 9–12 µm), *Ca. elaeagnicola* (21–23 × 8–10 µm), *Camarosporidiella elaeagnicola* (18–25 × 9–13 µm) and *Ca. arezzoensis* (22–30 × 8–10 µm)

have also been reported from *Elaeagnus* (Farr & Rossman 2017, this study). *Camarosporidiella elaeagnicola* and *Ca. arezzoensis* are also positioned in different subclades (Subclades A6 and A8 respectively, Fig. 1) and this provides additional support to justify their species status. The relationship between *Camarosporium caraganae* and *Ca. elaeagnicola* with *Camarosporidiella schulzeri* cannot be investigated due to lack of molecular data for *Camarosporium caraganae* and *Ca. elaeagnicola*.

Camarosporidiella spartii (Trail) Wijayaw., Wanas. & K.D. Hyde, **comb. nov.** MycoBank MB821961; Facesoffungi number: FoF 03549.

Basionym: *Camarosporium spartii* Trail, Scott. Natural., N.S. 3 ("9"): 222. 1888.

Illustrations: See [Wijayawardane et al. \(2014a\)](#).

Note: This species is located basal in Subclade A4 (Fig. 1).

Coniothyriaceae W.B. Cooke, Revista de Biol. 12: 289. 1983 ("1980–1983").

Type genus: *Coniothyrium* Corda.

Staurosphaeria Rabenh., Bot. Ztg. 16(40): 303. 1858. MycoBank MB5186; Facesoffungi number: FoF 03550.

Synonym: *Hazslinszkyomyces* Crous & R.K. Schumach, IMA Fungus 8: 143. 2017.

Necrotrophic or saprobic on dead branches. *Asexual morph:* *Conidiomata* solitary, globose, dark brown, immersed, erumpent, globose, with central ostiole; ostiolar canal filled with hyaline cells; conidiomatal wall of 6–8 layers of dark brown *textura angularis*. *Conidiophores* reduced to conidiogenous cells lining the inner cavity. *Macroconidiogenous cells* hyaline, smooth, doliform, proliferating percurrently at apex. *Macroconidia* solitary, ellipsoid, smooth, red-brown, with central transverse septum, becoming muriformly septate. *Microconidial cells* intermingled with macroconidial cells, hyaline, integrated, proliferating percurrently at apex, subcylindrical. *Microconidia* hyaline, globose to ellipsoid, smooth, aseptate. *Sexual morph:* cucurbitaria-like. *Ascomata* black, superficial to semi-immersed, gregarious, confluent, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, black, ostiolate. *Ostiole* central, short. *Peridium* composed of blackish to dark brown cells of *textura angularis*, cells towards the inside lighter, composed of thin-walled cells of *textura angularis*. *Hamathecium* comprising numerous, branched septate, *pseudoparaphyses*. *Asci* 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate. *Ascospores* overlapping uniseriate, muriform, mostly ellipsoidal, 4–6-transversely septate, with 1–2 vertical septa, constricted at middle septum, initially hyaline, becoming brown at maturity, slightly paler, conical and narrow at the ends.

Type species: *Staurosphaeria lycii* Rabenh.

Staurosphaeria lycii Rabenh., Bot. Ztg. 16(40): 303. 1858. Facesoffungi number: FoF 03551. [Figs 20, 21](#).

Necrotrophic on dead branches of *Lycium barbarum*. *Asexual morph:* *Conidiomata* pycnidial, 500–600 µm high, 500–650 µm diam ($\bar{x} = 570.4 \times 567.5$ µm, n = 10), solitary, black, immersed or partly erumpent, unilocular, ostiolate. *Ostiole* 150–200 µm long,

200–250 µm diam ($\bar{x} = 170.2 \times 235.4$ µm, n = 6), central, long, smooth, ostiolar canal filled with hyaline cells. *Pycnidial wall* multi-layered, 20–25 µm wide at the base, 25–30 µm wide in sides, thick, comprising 4–5 layers, with heavily pigmented outer layer, thick-walled, comprising blackish to dark reddish-brown cells of *textura angularis*, with lighter cells towards the inside, with inner layer composed of 1–2 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Macroconidiogenous cells* enteroblastic, annellidic, doliform, integrated, solitary, hyaline, smooth-walled, and formed from the inner layer of pycnidium wall. *Macroconidia* 11–16 × 9–11 µm ($\bar{x} = 13.1 \times 10.1$ µm; n = 40), globose to oblong, rounded at both ends, 1–2-transversely septate, with one longitudinal septum, muriform, smooth-walled, brown to dark brown. *Microconidiogenous cells* intermingled with macroconidiogenous cells, hyaline, integrated, enteroblastic, annellidic, ampulliform to subcylindrical. *Microconidia* 3.5–6.5 × 3.5–4.5 µm ($\bar{x} = 5.1 \times 4$ µm; n = 25), hyaline, round to oblong or ellipsoidal, with a few small guttules. *Sexual morph:* Undetermined.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, white, reverse creamy grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Material examined: **Germany**, Dresden, on dry branches of *Lycium barbarum* (*lectotype designated here*, Rabenh., Klotschii Herb. Viv. Mycol., Ed. nov., Ser. Prima, Cent. VIII, No. 736, in HAL). **Russia**, Rostov Region, Shakhty city, coal heap of former coal mine "Proletarian dictatorship", 47.7104113° N, 40.2627254° E, on dying and dead twigs of *Lycium barbarum* (Solanaceae), 21 May 2015, T.S. Bulgakov T-289 (MFLU 15-1993, *epitype designated here*, MBT377706, ex-type culture, MFLUCC 17-0210 = CBS 143140); *ibid.*, T-418 (MFLU 15-2122, living culture MFLUCC 17-0211 = CBS 143141).

Notes: The type species has very characteristic red-brown conidia, developing a transverse septum, and later vertical septa, dividing the conidium into four compartments. It is distinct from *Camarosporium* s. str. in that conidia in the latter are unevenly pigmented (pale brown at ends), and multi-septate, lacking a microconidial morph as observed in conidiomata of *Staurosphaeria*. It was in the past assumed that *Staurosphaeria* and *Karstenula* (*Didymosphaeriaceae*) are congeneric. However, the type species, *K. rhodostoma*, has been linked to the asexual morph *Microdiploidia frangulae* (Constantinescu 1993), so the generic synonymy with *Staurosphaeria* seems rather unlikely.

Other accepted species

Staurosphaeria aloes (Crous & M.J. Wingf.) Crous, Wanas. & K.D. Hyde, **comb. nov.** MycoBank MB821962; Facesoffungi number: FoF 03552.

Basionym: *Camarosporium aloes* Crous & M.J. Wingf., Persoonia 31: 247. 2013.

Synonym: *Hazslinszkyomyces aloes* (Crous & M.J. Wingf.) Crous, IMA Fungus 8: 143. 2017.

Illustrations and material examined: See [Crous et al. \(2013\)](#).

Illustrations and material examined: See [Crous & Groenewald \(2017\)](#).

Staurosphaeria lycicola (Crous & R.K. Schumach.) Crous, Wanas. & K.D. Hyde, **nom. nov.** MycoBank MB821964; Facesoffungi number: FoF 03554.

Basionym: *Hazslinszkyomyces lycii* Crous & R.K. Schumach., IMA Fungus 8: 144. 2017.

Illustrations and material examined: See [Crous & Groenewald \(2017\)](#).

Staurosphaeria rhamnicola Wanas., Gafforov & K.D. Hyde, **sp. nov.** MycoBank MB821965; Facesoffungi number: FoF 03555. **Fig. 22.**

Etymology: Named after the host genus from which it was collected, *Rhamnus*.

Saprobic on dead branches of *Rhamnus* sp. **Asexual morph:** Undetermined. **Sexual morph:** Ascomata 200–400 µm high, 250–350 µm diam ($\bar{x} = 320.4 \times 296.8$ µm, n = 10), black, superficial to semi-immersed, confluent, gregarious, sometimes scattered beneath the host periderm or on decorticated wood, fully or partly erumpent, globose, uniloculate, with an ostiole. Ostiole central, short, slightly sunken, minute and inconspicuous at the surface, smooth, ostiolar canal filled with hyaline cells. Peridium 25–40 µm wide at the base, 30–50 µm wide in sides, thick, comprising 8–12 layers, outermost layer heavily pigmented, thin-walled, comprising blackish to dark brown amorphous layer, middle layer heavily pigmented, thick-walled, comprising blackish to dark brown loosely packed cells of *textura angularis*, inner layer composed of 3–4 layers, reddish brown to hyaline, cells towards the inside lighter, flattened, thick-walled cells of *textura angularis*. Hamathecium comprising numerous,

2.5–3 µm (n = 40) wide, filamentous, branched septate, pseudoparaphyses. Ascii 170–200 × 16–22 µm ($\bar{x} = 186.2 \times 18.4$ µm, n = 40), 8-spored, bitunicate, fissitunicate, cylindrical, short-pedicellate, apex rounded with a minute ocular chamber. Ascospores 26–32 × 12–14 µm ($\bar{x} = 30.4 \times 13.1$ µm, n = 50), overlapping uniseriate, muriform, mostly ellipsoidal, 5–6-transversely septate, with 1–2 longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, asymmetrical, slightly paler ends, conical and narrowly rounded at the ends, not surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, creamy after 6 wk, reverse iron, flat on the surface, with aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Material examined: Uzbekistan, Surxondaryo Province, Sherobod District, Oqtosh village on dead twigs of *Rhamnus* sp. (Rhamnaceae), 12 May 2016, Y. Gafforov, YG-S4-4D (TASM 6102, **holotype**; *ibid.*, (MFLU 17-0183, **isotype**, ex-isotype culture MFLUCC 17-0814) *ibid.*, YG-S4-5 (TASM 6101 = MFLU 17-0182, **paratype**, ex-paratype culture, MFLUCC 17-0813).

Notes: *Staurosphaeria rhamnicola* morphologically resembles *Camarosporidiella arezzoensis*, *Ca. eufemiana*, *Ca. italicica*, *Ca. laburni*, *Ca. mirabellensis*, *Ca. premilcurensis* and *Neocucurbitaria acerina* in having similar ascomata, peridium, ascii and ascospore characters. However, they are phylogenetically distant from *Staurosphaeria rhamnicola* (Clade B, [Fig. 1](#)).

Neocamarosporiaceae Wanas., Wijayaw., Crous & K.D. Hyde, **fam. nov.** MycoBank MB821966; Facesoffungi number: FoF 03556.

Etymology: Referring to the name of the type genus.

Saprobic on leaves and wood. **Asexual morph:** Conidiomata immersed, becoming erumpent, globose, brown to black,

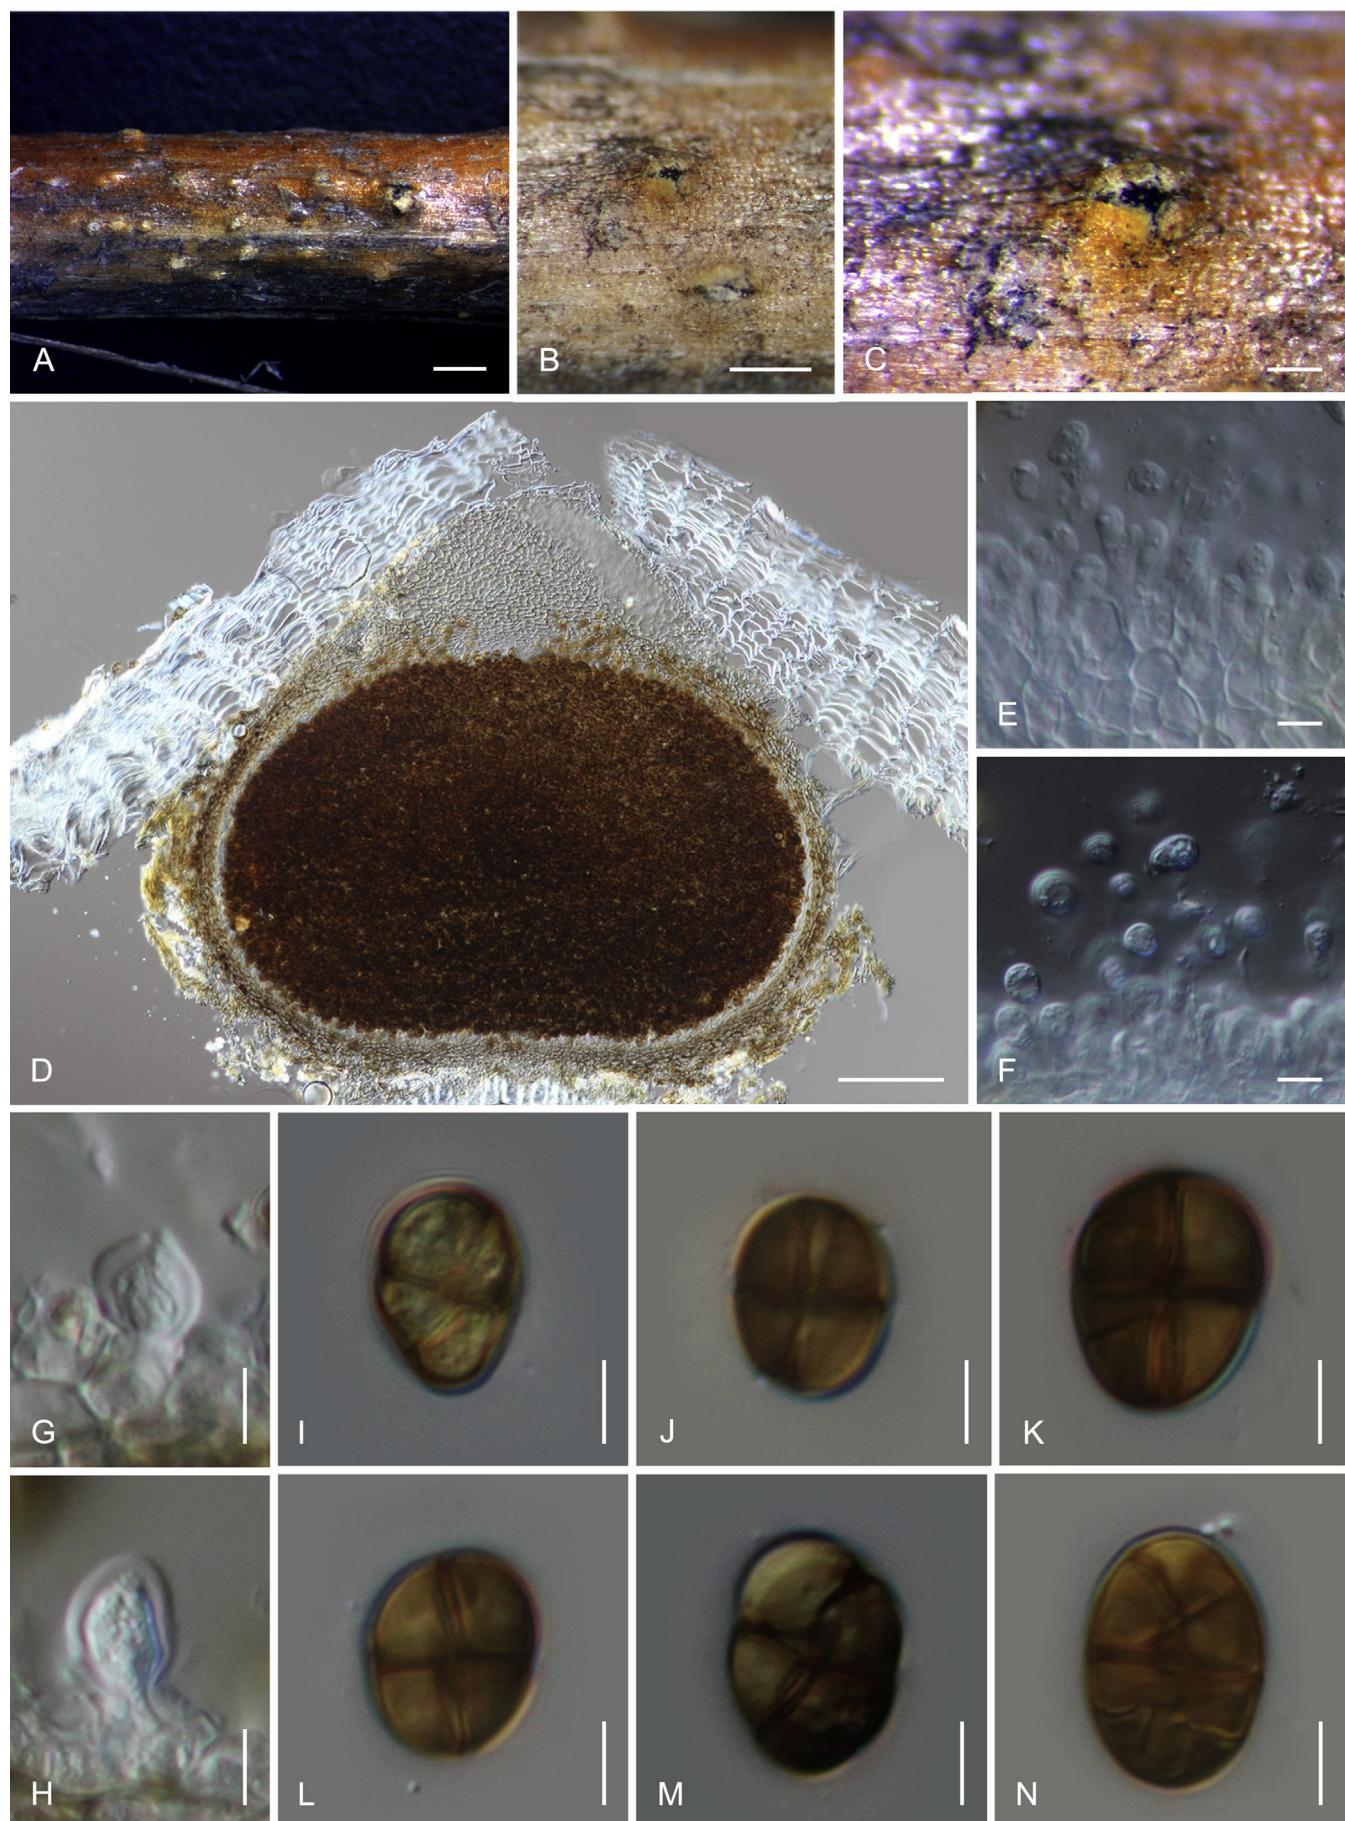

Fig. 21. *Stauropsphaeria lycii* (MFLU 15-1993, epitype). **A–C.** Conidiomata on host surface. **D.** Vertical section through conidioma. **E, F.** Microconidiogenous cells and microconidia. **G, H.** Macroconidiogenous cells. **I–N.** Macro conidia. Scale bars: A = 1 mm, B = 500 µm; C, D = 100 µm; E–N = 5 µm.

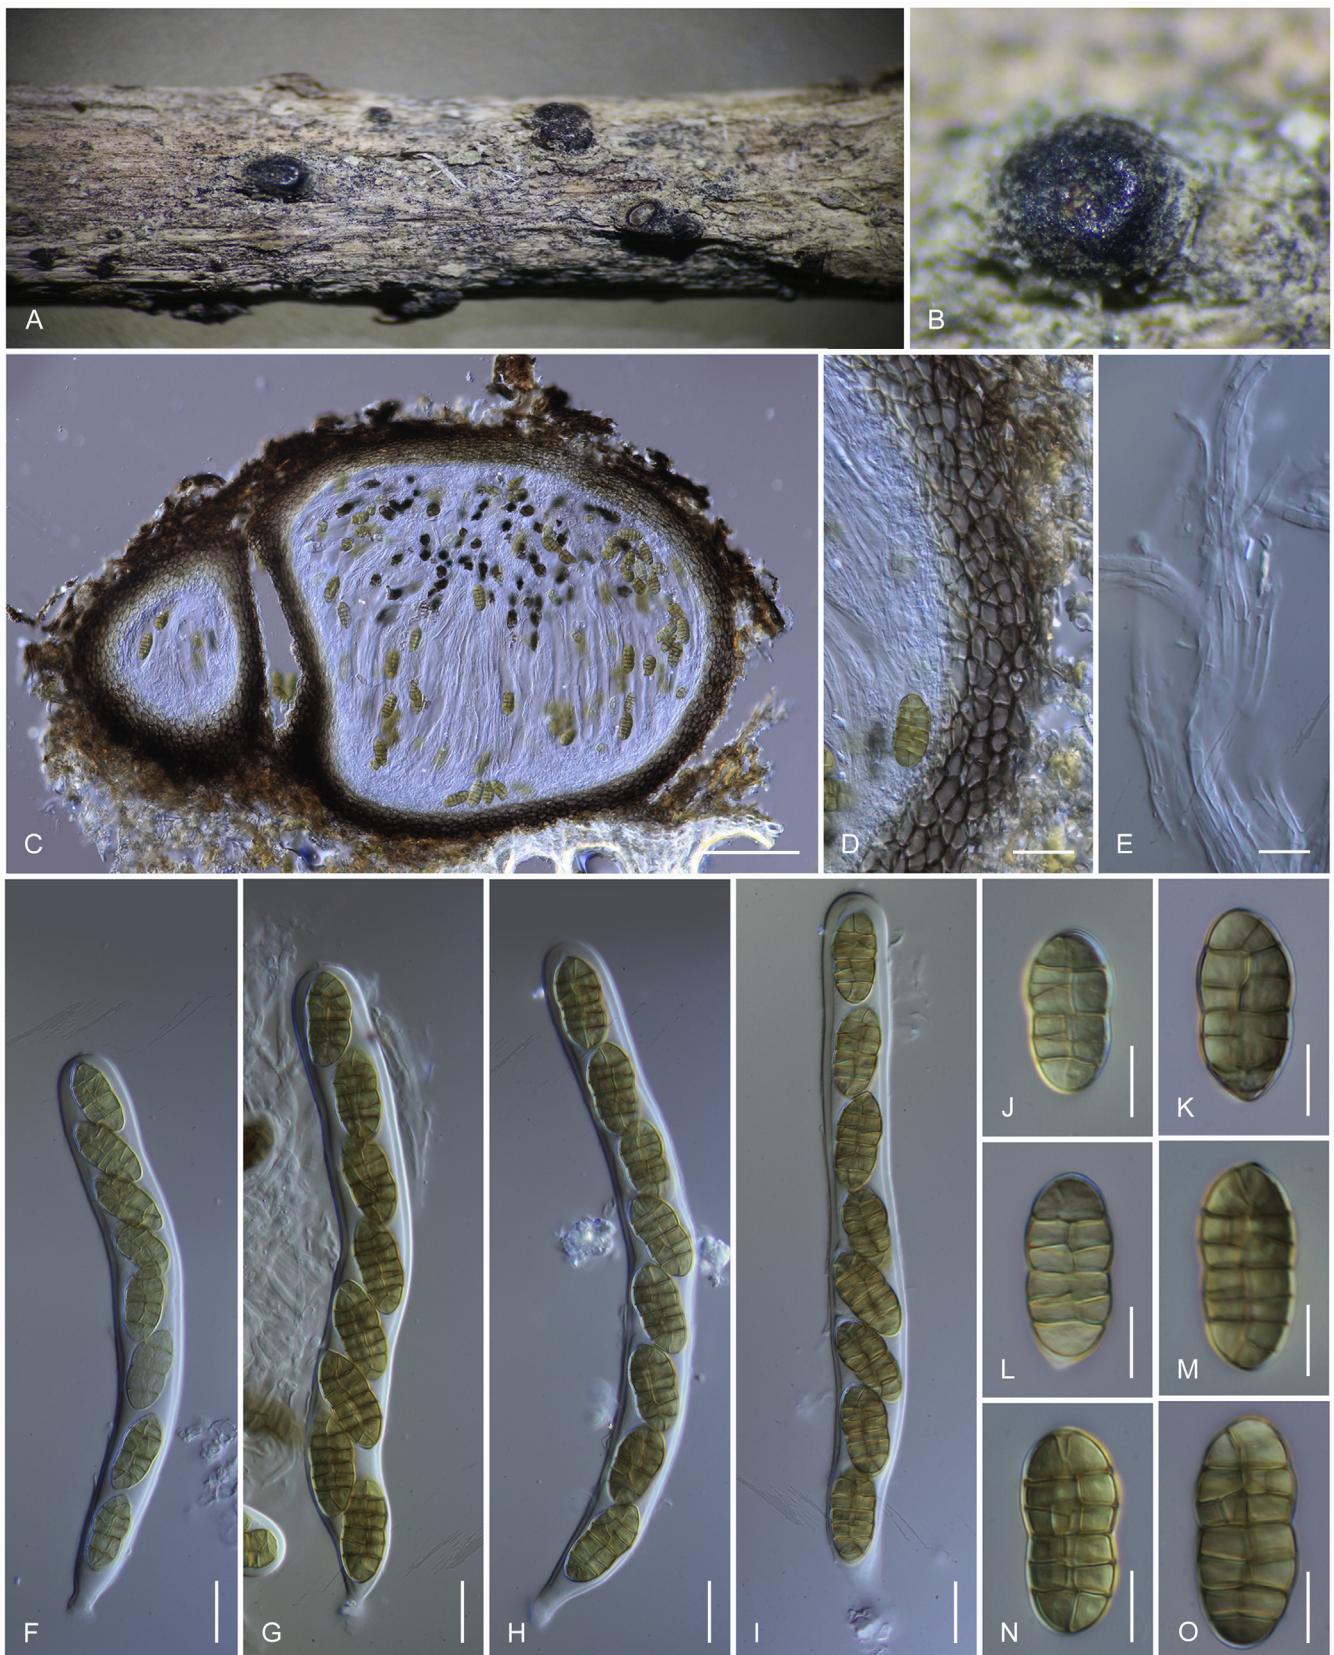

Fig. 22. *Staurosphaeria rhamnicola* (TASM 6102, holotype). **A, B.** Appearance of ascocarps on host substrate. **C.** Section of ascocarp. **D.** Peridium. **E.** Pseudoparaphyses. **F–I.** Ascii. **J–O.** Ascospores. Scale bars: C = 100 µm; D, F–I = 20 µm, E, J–O = 10 µm.

ostiolate. Ostiole papillate, central. Conidiomata wall composed of thin-walled, brown cells of *textura angularis*. Conidiophores reduced to conidiogenous cells. Conidiogenous cells proliferating several times percurrently near apex, ampulliform to doliform, separate, hyaline, smooth-walled. Conidia solitary, initially

hyaline, aseptate, developing initially a central septum and then becoming muriform, variable from globose to obovoid to ellipsoid, golden brown, finely roughened, thick-walled. Sexual morph: Ascomata superficial to semi-immersed, confluent, gregarious, fully or partly erumpent, globose, with an apapillate ostiole.

Ostiole central, short, erect or slightly sunken, smooth, ostiolar canal filled with hyaline cells. Peridium thin, comprising blackish to brown loosely packed cells of *textura angularis*. Hamathecium comprising numerous, filamentous, branched septate, pseudoparaphyses. Ascii 8-spored, bitunicate, fissitunicate, cylindrical-clavate to cylindrical, pedicellate, rounded at apex, with a minute ocular chamber. Ascospores uniseriate overlapping, muriform, mostly ellipsoidal, 5–7-transversely septate, with 1–2 longitudinal septa, deeply constricted at middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, rounded at both ends, surrounded by a mucilaginous sheath.

Type genus: *Neocamarosporium* Crous & M.J. Wingf.

Notes: Ariyawansa et al. (2015c) and Wijayawardene et al. (2016) treated *Neocamarosporium* as a genus in *Pleosporaceae*, but in our analyses four *Neocamarosporium* species, three new camarosporium-like taxa and a pleospora-like taxon also group with *Coniothyrium obiones*, *Dimorphosporicola tragani*, *N. chersinae*, *N. chichastianum*, *N. goegapense*, *Pleospora chenopodii*, *P. halimionae*, *P. calvescens*, *P. betae* and *Phoma betae* (which represent phoma-like and ascochyta-like asexual morphs *fide de Gruyter et al. 2012*) and reside in a distinct clade (Clade D, Fig. 1) in *Pleosporinae* with high bootstrap support (95 % and 79 % in ML and MP analyses respectively) and high PP value (1.00). This clade (Clade D) is distinct from *Pleosporaceae sensu stricto* which comprises *Pleospora sensu stricto* (= *Stemphylium*, see Woudenberg et al. 2017), the type genus. Therefore, *Neocamarosporiaceae fam. nov.* is introduced for Clade D based on morphology and multi-gene phylogeny.

The family *Neocamarosporiaceae* is somewhat similar to the *Pleosporaceae*, but differs in several respects. The characteristics of the ascromatal wall are distinctly different from each other. *Pleosporaceae* species have a thick peridium with several hyaline and pigmented cell layers, while *Neocamarosporiaceae* species have a thin peridium with only 2–3 pigmented cell layers and lack hyaline cell layers.

Ariyawansa et al. (2015c) mentioned that the asexual morphs of *Pleosporaceae* can be coelomycetous or hyphomycetous. Apart from *Neocamarosporium* (ascochyta-like, camarosporium-like and phoma-like) no other *Pleosporaceae* species produce a coelomycetous asexual morph. Therefore, it would appear that hyphomycetous asexual morphs are specific to *Pleosporaceae*. Therefore, by considering the sexual morph and asexual morph differences together with molecular support obtained herein with *Neocamarosporiaceae* in clade D, we believe that it would taxonomically be more appropriate to establish a new family to accommodate these species in *Pleosporinae*.

It is interesting to note that the species which were collected from marine to saline habitats, and produce muriform conidia, i.e. *Neocamarosporium chersinae*, *N. chichastianum* and *N. salicorniicola* cluster together as a subclade in clade D (Fig. 1), but could not be segregated from *Dimorphosporicola tragani* and *Coniothyrium obiones* based on our phylogenetic analyses. However, DNA sequence data of *Coniothyrium obiones* (CBS 453.68) analysed herein is an unverified sequence as it is not from the type material. Given that the relationship between the

Coniothyrium obiones and other taxa is undetermined, we keep CBS 453.68 as “*Coniothyrium*” *obiones* for now. *Dimorphosporicola tragani* is different to other taxa in *Neocamarosporium* in conidial morphology and habitat. Consequently, it would appropriate to retain *Dimorphosporicola* as a separate genus in *Neocamarosporiaceae*. Furthermore, some of the *Neocamarosporium* spp. (e.g. *N. chichastianum*) have only ITS sequence data and it would be wise to consider or evaluate the utility of several other genes such as large subunit nrDNA (28S, LSU), small subunit nrDNA (18S, SSU), or translation elongation factor alpha 1 (*tef1-a*) to further elucidate phylogenetic relationships among this clade of fungi with more fresh collections.

Neocamarosporium Crous & M.J. Wingf., Persoonia 32: 273. 2014. emend.

Saprobic on leaves and wood. Asexual morph: See Crous et al. (2014b). Sexual morph: Ascomata superficial to semi-immersed, confluent, gregarious, fully or partly erumpent, globose, with an apapillate ostiole. Ostiole central, short, erect or slightly sunken, smooth, ostiolar canal filled with hyaline cells. Peridium thin, comprising blackish to brown loosely packed cells of *textura angularis*. Hamathecium comprising numerous, filamentous, branched septate, pseudoparaphyses. Ascii 8-spored, bitunicate, fissitunicate, cylindrical-clavate to cylindrical, pedicellate, apex rounded with a minute ocular chamber. Ascospores overlapping uniseriate, muriform, mostly ellipsoidal, 5–7-transversely septate, with 1–2-longitudinal septa, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, rounded at both ends, surrounded by a mucilaginous sheath.

Type species: *Neocamarosporium goegapense* Crous & M.J. Wingf.

Notes: The genus *Neocamarosporium* was introduced by Crous et al. (2014b) based on *Neocamarosporium goegapense* from South Africa, which is morphologically similar to the genus *Camarosporium* with its pycnidial conidiomata, hyaline, percurrently proliferating conidiogenous cells, and brown, muriform conidia (Crous et al. 2014b). Currently there are 25 strains that cluster in *Neocamarosporium*, representing 11 species (in this study). Also, a further three strains which was introduced by Grum-Grzhimaylo et al. (2016) and six strains which were collected from marine to saline habitats in Iran, group here as *Neocamarosporium* sp. In this study, we introduce *Neocamarosporium korpii*, *N. lamiacearum* (first sexual record), *N. salicorniicola* and *N. salsolae* as new species in *Neocamarosporium*.

Accepted species in *Neocamarosporium*

Neocamarosporium betae (Berl.) Ariyawansa & K.D. Hyde, Fungal Diversity 71: 119. 2015.

Basionym: *Pyrenophora echinella* var. *betae* Berl.: 208. 1888.

Neocamarosporium obiones (Jaap) Wanas. & K.D. Hyde, **comb. nov.** MycoBank MB821968; Facesoffungi number: FoF 03558.

Basionym: *Diplodina obiones* Jaap, Verh. bot. Ver. Prov. Brandenb. 47: 96. 1905.

Synonyms: *Ascochyta obiones* (Jaap) P.K. Buchanan, Mycol. Pap. 156: 28. 1987.

Pleospora halimionae Gruyter & Verkley, Stud. Mycol. 75: 25. 2012.

Neocamarosporium korfii Wanas., E.B.G. Jones & K.D. Hyde, **sp. nov.** MycoBank MB821969; Facesoffungi number: FoF 03559. [Fig. 23](#).

Etymology: In honour of Prof. Richard Paul “Dick” Korf (May 28, 1925 – August 20, 2016) for his immense contribution to mycology.

Saprobic on dead stems. *Asexual morph:* *Conidiomata* pycnidial, 130–200 µm high, 160–220 µm diam ($\bar{x} = 161.7 \times 178.9$ µm, n = 10), solitary or gregarious, black, superficial, unilocular. *Ostiole* inconspicuous. *Pycnidial wall* 12–20 µm wide, comprising 3–5 layers, outer layer heavily pigmented, thick-walled, comprising dark brown cells of *textura angularis*, cells towards the inside lighter, inner layer comprising 2–3 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* enteroblastic, annellidic, doliiform, integrated, solitary, hyaline, smooth-walled, and originated from the inner layer of pycnidium wall. *Conidia* 12–18 × 8–10 µm ($\bar{x} = 14.3 \times 9.4$ µm; n = 30), oblong, straight to slightly curved, rounded at both ends, 1–3-transversely septate, with 1–2 longitudinal septa, muriform, smooth-walled, dark brown, guttulated. *Sexual morph:* Undetermined.

Colonies on PDA: Slow growing, reaching 3 cm diam after 3 wk at 16 °C, powdery, circular, smooth margin, greenish brown, reverse dark brown.

Material examined: Russia, Republic of Crimea, Feodosia city Municipality, Karadag State Nature Reserve, 44°9145837°N, 35°2025127°E, on dead branches of *Bassia prostrata* (Amaranthaceae), 23 Jun. 2016, T.S. Bulgakov CR006 (MFLU 17-1436 **holotype**, ex-type culture MFLUCC 17-0745 = CBS 143135).

Notes: Based on the multi-gene phylogenetic analyses ([Fig. 1](#)), our strain of *Neocamarosporium korfii* segregates from *N. lamiacearum*, but this subclade is not supported in the phylogenetic analyses (Clade D, [Fig. 1](#)). *Neocamarosporium korfii* is morphologically similar to *N. salsolae* and *N. salicorniae-cola* in conidiomatal characteristics and conidial shape. However, these species are phylogenetically distinct (Clade D, [Fig. 1](#)). Thus, in this paper we introduce *N. korfii* as a new species in *Neocamarosporium*.

Neocamarosporium lamiacearum Dayar., E.B.G. Jones & K.D. Hyde, **sp. nov.** MycoBank MB821970; Facesoffungi number: FoF 03560. [Fig. 24](#).

Etymology: Named after the host family from which it was collected, Lamiaceae.

Saprobic on dead stems of Lamiaceae sp. *Asexual morph:* Undetermined. *Sexual morph:* *Ascomata* 200–250 µm high, 180–250 µm diam ($\bar{x} = 232.1 \times 217.4$ µm, n = 10), black, superficial to semi-immersed, confluent, gregarious, cupulate when dry, globose, uniloculate, with an apapillate ostiole. *Ostiole*, 40–60 µm long, 40–60 µm diam, central, short, slightly sunken, minute and inconspicuous at the surface, smooth, ostiolar canal filled with hyaline cells. *Peridium* 10–15 µm wide at the base, 10–20 µm wide in sides, thin, comprising 2–3 layers, reddish brown to brown, cells towards the inside lighter, flattened, thin-walled cells of *textura angularis*. *Hamathecium* comprising numerous, 2.5–3 µm (n = 40) wide, filamentous, branched, septate, pseudoparaphyses. *Asci* 100–120 × 14–17 µm ($\bar{x} = 105.5 \times 15$ µm, n = 40), 8-spored, bitunicate, fissitunicate, cylindrical-clavate to cylindrical, pedicellate (10–20 µm long), apex rounded with a minute ocular chamber. *Ascospores* 14–20 × 8–11 µm ($\bar{x} = 15.9 \times 9.4$ µm, n = 50), overlapping uniseriate, muriform, mostly ellipsoidal, with 3–4-transversely septate, with one longitudinal septum, deeply constricted at the middle septum, slightly constricted at remaining septa, initially hyaline, becoming pale brown at maturity, upper part wider than lower part, slightly paler, rounded at both ends, conical at lower end, surrounded by a mucilaginous sheath.

Colonies on PDA: Slow growing, reaching 2 cm diam after 4 wk at 16 °C, later with dense mycelium, circular, rough margin, white, reverse cream-grey, flat on the surface, without aerial mycelium. Hyphae septate, branched, hyaline, thin-walled.

Materials examined: Russia, Rostov Region, Krasnosulinsky district, Donskoye forestry, 47°8547249°N, 40°2318907°E, steppe in gully, on dead stems of Lamiaceae plant (perhaps, *Marrubium peregrinum* or *Phlomis herba-venti* ssp. *pungens*), 28 Jun. 2015, T.S. Bulgakov T-846 (MFLU 15–2989, **holotype**, ex-type culture MFLUCC 16-0560 = CBS 143136); Russia, Republic of Crimea, Feodosia city Municipality, salt-march near Baraqol salty lake, 44°9963682°N, 35°2431965°E, on dead branches of *Bassia sedoides* (Amaranthaceae), 23 Jun. 2016, T.S. Bulgakov CR026 (MFLU 17-1437, **paratype**, ex-paratype culture, MFLUCC 17-0750 = CBS 143137).

Notes: *Neocamarosporium lamiacearum* is morphologically somewhat similar to taxa in Pleosporaceae in having cylindrical-clavate to cylindrical ascii and muriform ascospores. However, the characteristics of the ascromatal wall in *Neocamarosporium*

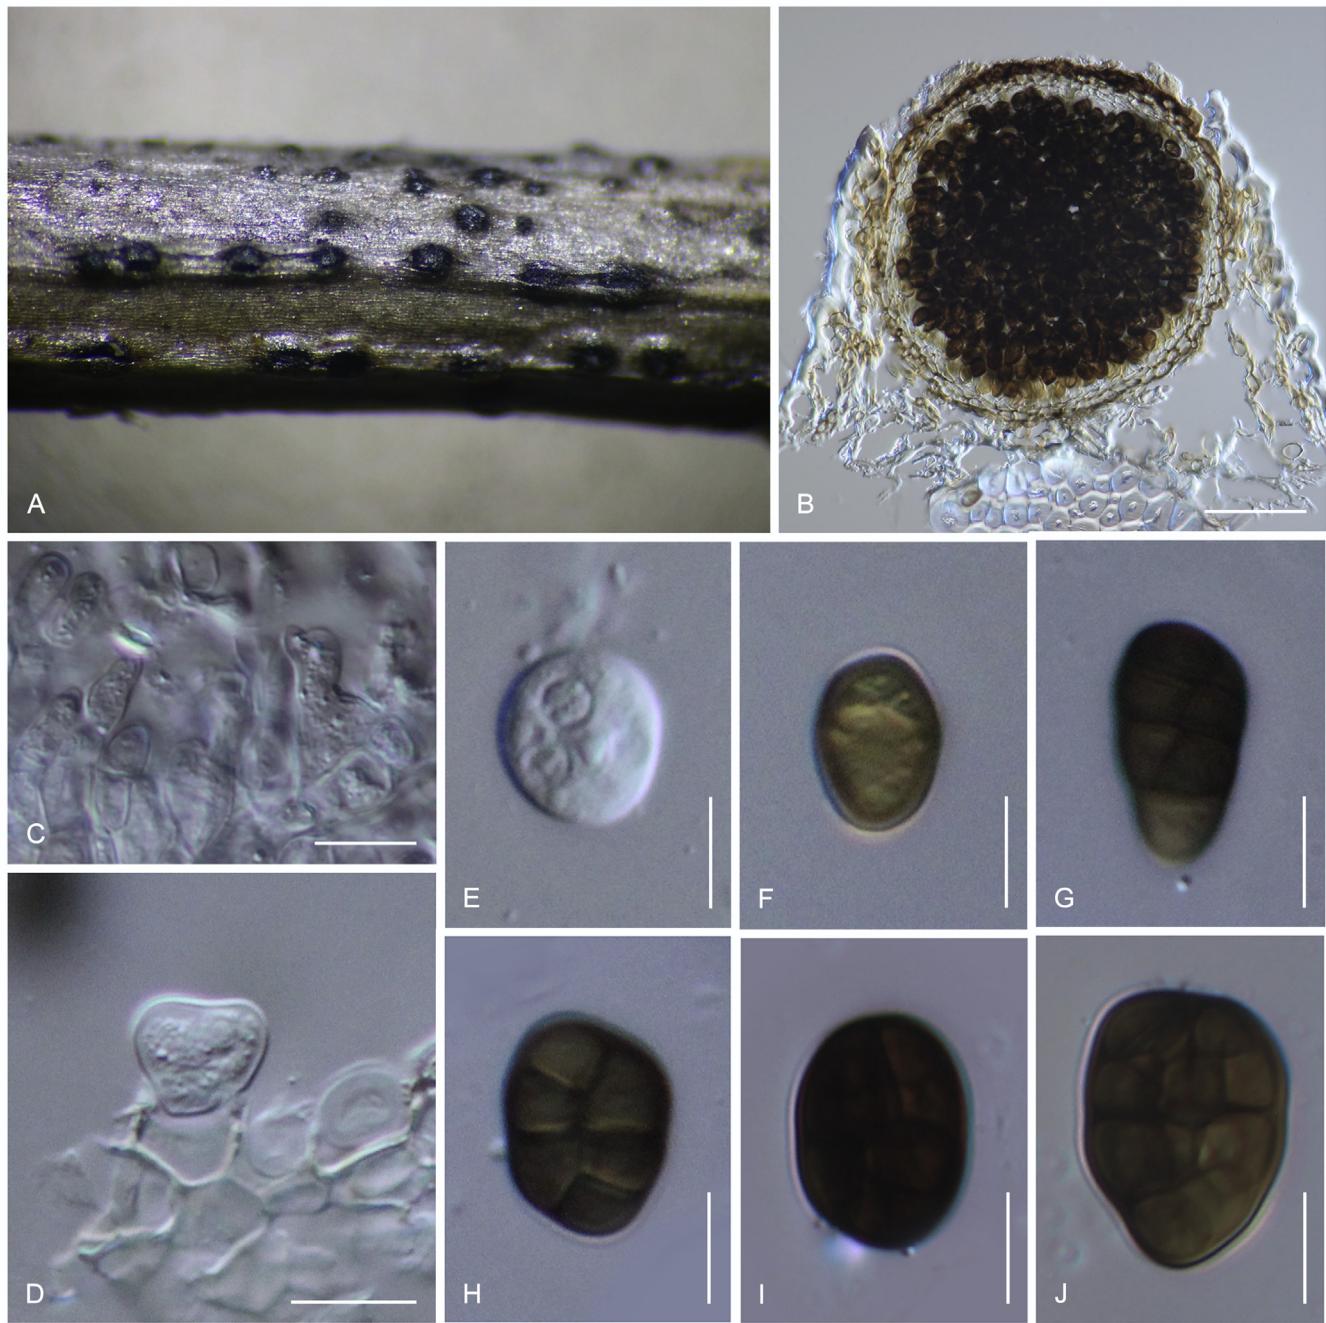

Fig. 23. *Neocamarosporium korpii* (MFLU 17-1436, holotype). **A.** Appearance of conidiomata. **B.** Vertical section of conidioma. **C, D.** Conidiogenous cells. **E–J.** Conidia. Scale bars: B = 50 µm; C, D = 10 µm; E–J = 5 µm.

lamiacearum are noticeably different from *Pleosporaceae* taxa. *Pleosporaceae* species have a thick peridium with several hyaline and pigmented cell layers, while *Neocamarosporiaceae lamiacearum* has a thin peridium with only 2–3 pigmented cell layers and lack hyaline cell layers.

Neocamarosporium salicorniicola Dayarathne, E.B.G. Jones & K.D. Hyde, sp. nov. MycoBank MB821971; Facesoffungi number: FoF 03561. [Fig. 25](#).

Etymology: Named after the host genus from which it was collected, *Salicornia*.

Saprobic on dead stems of *Salicornia* sp. **Asexual morph:** *Conidiomata* pycnidial, 75–110 µm high, 80–96 µm diam ($\bar{x} = 94.4 \times 88 \mu\text{m}$, n = 10), solitary or gregarious, black, superficial, unilocular. *Ostiole* inconspicuous. *Pycnidial wall* 7–11 µm wide, comprising 3–4 layers, outer layer heavily pigmented, thick-

walled, comprising dark brown cells of *textura angularis*, cells towards the inside lighter, inner layer comprising 2–3 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* enteroblastic, annelidic, doliform, integrated, solitary, hyaline, smooth-walled, and originated from the inner layer of pycnidium wall. *Conidia* 8–12 × 4–6 µm ($\bar{x} = 10.5 \times 4.8 \mu\text{m}$; n = 30), oblong, straight to slightly curved, rounded at both ends, 1–3-transversely septate, with one longitudinal septum, muriform, smooth-walled, dark brown, guttulated. **Sexual morph:** Undetermined.

Colonies on PDA: Slow growing, reaching 3 cm diam after 3 wk at 16 °C, powdery, circular, smooth margin, ash, reverse yellowish at margins and black at the middle.

Material examined: Thailand, Phetchaburi Province, Cha-Am, Chao Samran, on dead stem of *Salicornia* sp. (Amaranthaceae), 28 Jul. 2015, M. Dayarathne CHAM025 (MFLU 15-0957, **holotype**, ex-type culture MFLUCC 15-0957).

Fig. 24. *Neocamarosporium lamiacearum* (MFLU 15-2989, holotype). **A, B.** Appearance of ascomata on host substrate. **C.** Section of ascoma. **D.** Peridium. **E.** Pseudo-paraphyses. **F–H.** Ascii. **I–L.** Ascospores. Scale bars: A, B = 200 µm; C = 100 µm; D, E = 10 µm; F–H = 20 µm; I–L = 10 µm.

Notes: Based on the multi-gene phylogenetic analyses (Fig. 1), our strain of *N. salicorniicola* shares a sister relationship to *N. jorjanensis* and to *Dimorphosporicola tragani* but with no support (Clade D, Fig. 1). In this paper, we introduce *Neocamarosporium salicorniicola* as a new species in *Neocamarosporium*, based on its comparatively smaller and distinct dark, guttulate conidia, and its phylogenetic position.

Neocamarosporium salsolae Wanas., Gafforov & K.D. Hyde, sp. nov. MycoBank MB821972; Facesoffungi number: FoF 03562. Fig. 26.

Etymology: Named after the host genus from which it was collected, *Salsola*.

Saprobic on dead stems of *Salsola* sp. **Asexual morph:** *Conidiomata* pycnidial, 120–150 µm high, 80–110 µm diam ($\bar{x} = 137.5 \times 99.5$ µm, n = 10), solitary or gregarious, black, superficial, unilocular. *Ostiole* inconspicuous. *Pycnidial wall* 6–10 µm wide, comprising 3–4 layers, outer layer heavily pigmented, thick-walled, comprising dark brown cells of *textura angularis*, cells towards the inside lighter, inner layer comprising 2–3 layers, hyaline, thin-walled cells of *textura angularis*. *Conidiophores* reduced to conidiogenous cells. *Conidiogenous cells* enteroblastic, annellidic, doliiform, integrated, solitary, hyaline, smooth-walled, and originated from the inner layer of pycnidium wall. *Conidia* 18–25 × 12–20 µm ($\bar{x} = 21.9 \times 16.9$ µm; n = 30), oblong, straight to slightly curved, rounded at both ends, 1–3 transversely septate, with 1–3 longitudinal septa, muriform, smooth-walled, dark brown. **Sexual morph:** Undetermined.

Colonies on PDA: Slow growing, reaching 3 cm diam after 3 wk at 16 °C, circular, smooth margin, dark green, reverse blackish green.

Materials examined: **Uzbekistan**, Surxondaryo Province, Sherobod District, Oqtosh village on dead stem of *Salsola* sp. (Amaranthaceae), 12 May 2016, Y. Gafforov YG-S6-(TASM 6100, holotype); *ibid.*, (MFLU 17-0192, isotype, ex-isotype culture MFLUCC 17-0827) *ibid.*, YG-S6-1 (TASM 6099 = MFLU 17-0191, paratype, ex-paratype culture, MFLUCC 17-0826).

Notes: Based on the multi-gene phylogenetic analyses (Fig. 1), our strains of *Neocamarosporium salsolae* cluster in a subclade sister to *N. goegapense* with significant statistical support (Clade D, Fig. 1).

Another accepted genus

Dimorphosporicola Crous, Fungal Biology 120: 1412.

Type species: *Dimorphosporicola tragani* Crous.

Dimorphosporicola tragani Crous, Fungal Biology 120: 1413.

Illustrations and material examined: See Crous & Groenewald (2016).

Notes: *Dimorphosporicola* was described by Crous & Groenewald (2017) to accommodate *D. tragani*, which is morphologically similar to *Coleophoma* species. But *D. tragani* is distinct from *Coleophoma* by having percurrently proliferate conidiogenous cells, and having dimorphic conidia.

Dimorphosporicola and *Neocamarosporium* are different to each other in macro-conidial morphology.

DISCUSSION

Our phylogenetic results indicate that camarosporium-like species which were treated as *Camarosporium* in previous papers (viz. *Camarosporium arezzoensis*, *Cm. aborescentis*, *Cm. caraganicola*, *Cm. elaeagnellum*, *Cm. elongata*, *Cm. clematidis*, *Cm. spartii*, *Cm. robbiniicola* and *Cm. aureum* *fide* Wijayawardene et al. 2014a, c, Liu et al. 2015, Tibpromma et al. 2016, Thambugala et al. 2016) are well positioned within the *Pleosporineae* and phylogenetically distinct from other genera. These species, which has been our focal group, constitute a strongly supported monophyletic lineage with 75 newly collected strains (Clade A). In contrast, *Cm. quaternatum* (CPC 23216, CPC 31081 & CPC 31518), the type species of *Camarosporium*, and other camarosporium-like taxa group in separate clades (Clade A, B, C and D, Fig. 1).

To discuss tree output (Fig. 1), we divided the taxa in the phylogram into 4 clades (A–D), and ingroup taxa in Clade A into 12 subclades (A1–A12). Generally, *Camarosporidiella* clustered separately from the rest with high support (Clade A, Fig. 1). All species in Clade A are distinct from other camarosporium-like taxa in *Pleosporineae*. Clade A comprises new strains and several other species were transferred to the new genus, *Camarosporidiella* (Fig. 1). With regards to conidial morphology, *Camarosporidiella* resembles *Camarosporium sensu stricto* and other camarosporium-like genera (Crous et al. 2014b, 2015a, b, Wijayawardene et al. 2014c, 2015, 2016) but is phylogenetically distinct. *Camarosporidiella arezzoensis*, *Ca. aborescentis*, *Ca. caraganicola*, *Ca. celtidis*, *Ca. eufemiana*, *Ca. elongata*, *Ca. italica*, *Ca. laburni*, *Ca. mirabellensis* and *Ca. premilcurensis* represent the sexual morph of the genus. Thus, the holomorph of the genus comprises a camarosporium-like asexual morph and cucurbitaria-like sexual morph. With the addition of new specimens and species, updated morphological characterisation, DNA sequence data analyses with strong support, and the monophyletic status of *Camarosporidiella* species, a new family, *Camarosporidiellaceae* is established herein to circumscribe *Camarosporidiella*.

Clade B comprises two new collections which are morphologically similar to *Staurosphaeria lycii* and three other species i.e. *Hazslinszkyomyces lycii*, *H. aptrootii* and *H. aloes* in *Coniothyriaceae* with significant statistical support. By giving precedence to the oldest name, the genus *Staurosphaeria* is resurrected to accommodate this group. Clade C (Fig. 1), which comprises the type species of *Camarosporium*, is retained as *Camarosporium sensu stricto* and *Camarosporomyces flavigenus*. As in Wijayawardene et al. (2014b) and Crous & Groenewald (2017), *Camarosporium sensu stricto* groups with *Coniothyriaceae*, which comprises *Coniothyrium sensu stricto* and phoma-like species (de Gruyter et al. 2012). Recent studies reported that some camarosporium-like genera (such as *Pseudocamarosporium* and *Paracamarosporium*) have broader generic concepts (Crous et al. 2015a, b). Wijayawardene et al. (2014c) introduced *Pseudocamarosporium* and *Paracamarosporium* to accommodate camarosporium-like taxa that reside in *Didymosphaeriaceae*. Crous et al. (2015b) showed that several *Coniothyrium*-like species group with *Pseudocamarosporium* and

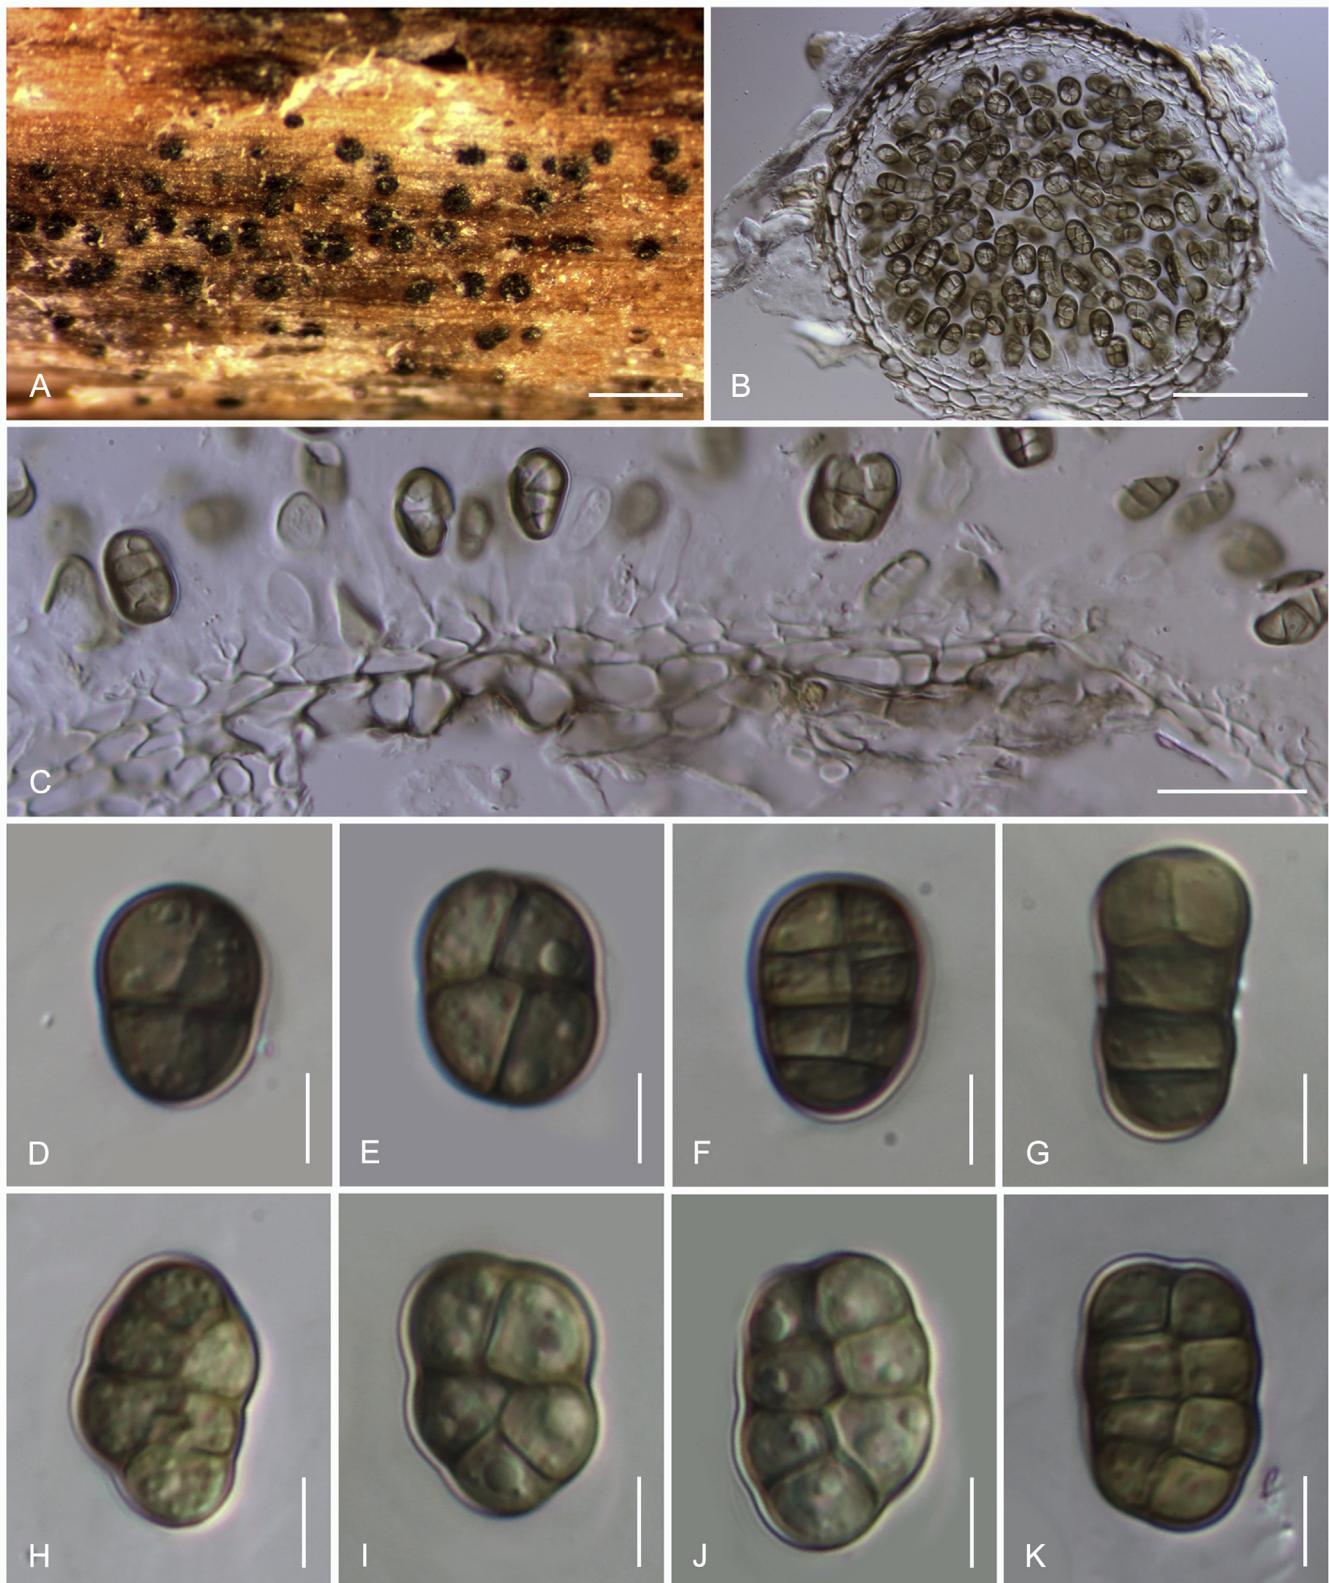

Fig. 25. *Neocamarosporium salicorniicola* (MFLU 15-0957, holotype). **A.** Appearance of conidiomata on *Salicornia* sp. **B.** Vertical section of conidioma. **C.** Developing stages of conidia on conidiogenous cells. **D–K.** Conidia. Scale bars: B = 50 µm; C = 20 µm; D–K = 5 µm.

Paracamarosporium in their phylogenetic study. Hence, both *Pseudocamarosporium* and *Paracamarosporium* exhibit camarosporium-like or coniothyrium-like conidial morphologies. Further phylogenetic investigations with broader taxon sampling of *Camarosporium sensu stricto* and *Coniothyrium sensu stricto* are warranted to better understand both the *Camarosporium* and *Coniothyrium* generic concepts.

Neocamarosporium goegapense and 10 other *Neocamarosporium* species cluster in a strongly supported clade (Clade D, Fig. 1). Based on morphology of the sexual and asexual morphs and multi-gene phylogeny, *Neocamarosporiaceae* was introduced. Previous studies and our results in this study demonstrate that naming of camarosporium-like taxa based only on morphology is inaccurate and hence there is a need to carry

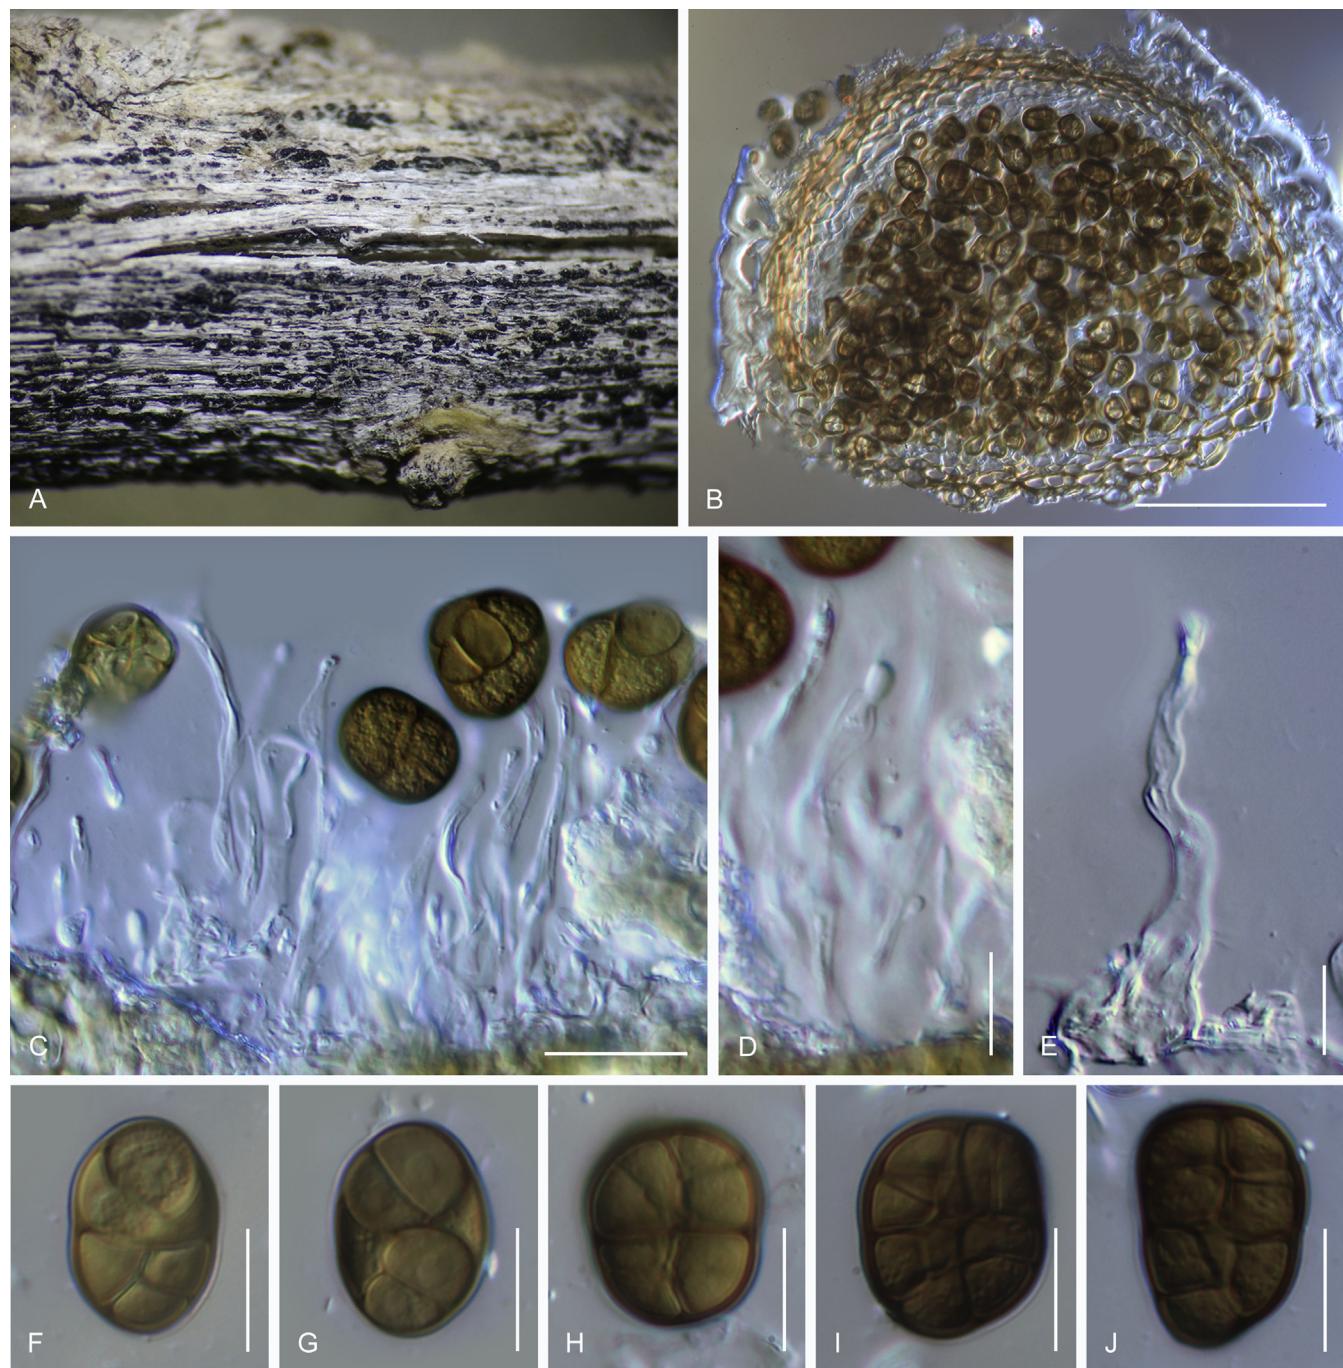

Fig. 26. *Neocamarosporium salsolae* (TASM 6100, holotype). **A.** Appearance of conidiomata on *Salsola* sp. **B.** Vertical section of conidioma. **C–E.** Conidiogenous cells and developing conidia. **F–J.** Conidia. Scale bars: B = 50 µm; C = 20 µm; D–J = 10 µm.

out DNA sequence-based studies. [Wijayawardene et al. \(2016\)](#) discussed the importance of re-collecting, and epitypifying of camarosporium-like taxa as currently it has more than 500 epithets in Index Fungorum (2017), and very few of these taxa are presently known from culture.

ACKNOWLEDGEMENTS

We thank the technical staff of Center of Excellence in Fungal Research, Somram Supkisit, Wilawan Punyaboon and Thatsanee Luangham for their invaluable assistance. We are also grateful to Milan C. Samarakoon, Danushka Tennakoon, Indunil C. Senanayake, Asha J. Dissanayake, Qing Tian, Chuan-Gen Lin for their valuable assistance with the culture work, DNA isolation, amplification and sequencing. Dhanushka Wanasinghe is thankful to Hiran Ariyawansa for his valuable suggestions. Chayanard Phukhamsakda would like to thank Royal Golden Jubilee Ph. D. Program under Thailand Research Fund,

for the award of a scholarship no. PHD/0020/2557 to study towards a PhD. Alan JL Phillips acknowledges the support from Biosystems and Integrative Sciences Institute (BioISI, FCT/UID/Multi/04046/2013). R. Jeewon is grateful to University of Mauritius & Mae Fah Luang University for enabling research collaboration. K.D. Hyde thanks to National Research Council of Thailand (Mae Fah Luang University) for grants “Biodiversity, phylogeny and role of fungal endophytes of *Pandanaceae*” (Grant No: 592010200112) and Thailand Research Fund (TRF) grant no RSA5980068 entitled “Biodiversity, phylogeny and role of fungal endophytes on above parts of *Rhizophora apiculata* and *Nypa fruticans*”. National Research Council of Thailand (Mae Fah Luang University) grant no 60201000201 entitled “Diseases of mangrove trees and maintenance of good forestry practice”. Samantha C. Karunarathna thanks to Yunnan Provincial Department of Human Resources and Social Security funded postdoctoral project (number 179122). Kevin D. Hyde also thanks to the Chinese Academy of Sciences, project number 2013T2S0030, for the award of Visiting Professorship for Senior International Scientists at Kunming Institute of Botany. Y.S. Gafforov acknowledges the support from Committee for

coordination science and technology development under the Cabinet of Ministers of Uzbekistan (Project No. P3-2014-0830174425).
