THE (NON)-EFFECT OF THE KNOWLEDGE ERA ON UNDER-GRADUATE RESEARCH METHODOLOGY CURricula IN THE SOCIAL SCIENCES

CLAIRE WAGNER
DAVID JF MAREE
Department of Psychology
University of Pretoria

ABSTRACT
Educational policy reform in South Africa seeks to address the real-life relevance of curricula, and specifically, reformists have turned to proponents of Mode 2 knowledge to inform initiatives for change. This study aimed to explore the extent to which trends in the knowledge production requirements for higher education are reflected in the beliefs held by academics about the way in which they construct under-graduate research courses. It is proposed that the way forward for curriculum construction lies in establishing academic communities of practice where academics share power and are open to the challenges that they face such as negotiating what is accepted as knowledge.

OPSOMMING
Opvoedkundige beleidshervorming in Suid-Afrika poog om die praktiese toepaslikheid van kurrikula aan te spreek. Reformistes het toegeskakel na pleiters van Mode 2 kennis om initiatiewe vir verandering te informeer. Hierdie studie het die mate waarin tendense in die vereistes vir kennisproduksie vir hoër onderwys in die oortuigingsstrukture van akademici oor die manier wat hulle voorgraadse navorsingskursusse saamstel, aangetoon. Dit word voorgestel dat die akademiese gemeenskappe wat praktikergereik is, gesetel word. Hier kan akademici mag deel en uitdaginge, soos wat as kennis gereken kan word, aanspreek.
management, while delivery of education takes place via face-to-face contact. In contrast, the latter type of institution is more open to different groups of people, encourages partnerships with government, the private sector and other major economic or social role-players, and offers many types of modes of delivery. Most importantly, the organisation of learning is not limited to interaction within a discipline, but occurs across fields and even institutions. This makes knowledge trans-disciplinary as it includes elements from all disciplines into a type of hybridised science that cannot be fitted back into the separate subjects of Mode 1 learning.

This trans-disciplinary and trans-institutional nature of Mode 2 is, according to Gibbons et al. (1994) and Scott (1995), what characterises the new way in which organisations will function. Knowledge is not something held within elite academic circles for the sake of academia, but it is generated within the context of real-world problems that need to be solved in industry. Hence, Kraak (2000) refers to these solutions as ‘socially accountable knowledge’ because of their meaningful contribution to society or their applications in industry. The solutions are also characterised by heterogeneity in that different processes are used in innovative ways to find answers. The implication of the above discussion is that learners who enter higher education systems should exit as trans-disciplinary problem solvers and innovative knowledge producers. According to Kraak (2000), the various policies mentioned imply that Mode 2 research is more useful to address the demands of the current world economy and thus should be ranked above Mode 1 research. This position has, however, been questioned by some individuals and a critique is set out below.

Should mode 2 learning and research be afforded a privileged place in higher education?

The heading of this section asks the important question of whether Mode 2 should supplant Mode 1 education and research in tertiary institutions. Should educators uncritically accept a different way of structuring learning and change curricula by developing programmes that are flexible, transdisciplinary, focused on problem-solving, interdependent, relevant to a specific context, funded from many sources and so on (issues that will be elaborated on below)? In other words, this position accepts that Mode 2 knowledge production has profound implications for the way in which we teach students and the knowledge they will need to compete in a society that demands specific kinds of skills. Another assumption that is made, for example, is that there are vast differences between the current curriculum and the type of syllabus that proponents of Mode 2 would put forward. Muller (2000, p. 50) warned that “[a]cademics may for convenience simply teach their Mode 2 involvements instead of what the curriculum requires” and that academics will be less involved with students as a result of commitments to their own research agendas. An academic’s position as a research consultant to various sectors of society may thus be afforded a privileged place and affect the kind of teaching that they do (Brew, 2003). An advantage of this may be that students will receive more up-to-date content in the curriculum and thus be better prepared for the types of positions they will occupy in the real world of work (Muller, 2000).

On a higher level than curriculum design, Robins and Webster (1999) identified a crucial point regarding the future of the university within the context of a post-Fordist society. It is Robins and Webster’s contention that the characteristics of this economically driven era (constant change, for example) are defining the learning that is taking place at some universities. Learning programmes are thus being adjusted to suit an economic agenda. Also, universities have been influenced by international trends of societies that hold institutions accountable for how they spend their money. In this environment, business traditions are mimicked in order to generate non-governmental income and the marketisation (or commercialisation) of higher education takes place to avoid the criticism that “universities have not managed to supply appropriate outputs, that graduates have most conspicuously lacked the ‘transferable personal skills’ that would make them useful to employers” (Robins & Webster, 1999, p. 196). In South Africa “governments and employers are calling on education providers to develop generic transferable skills in learners” (Department of Education, 2002). To facilitate this, the Department of Education (DoE) has written generic level descriptors to describe these skills so that they can be developed and integrated into specific curricula. Mode 2 subscribes to this marketisation agenda as it focuses strongly on partnerships with industry and delivering students with skills that will fulfil industrial needs. Critics of this trend, such as Slaughter and Leslie (1997), have pointed out what they believe the consequence will be of the wholesale adoption of Mode 2: the destruction of traditional academic goals, what Robins and Webster (1999) referred to as ‘narratives of decline’. For example, research for its own sake will be replaced by research that can serve the purposes of industry.

An added dimension to this phenomenon is the freedom that post-Fordism affords adherents of post-modernism to advocate the post-modern university. If society is ‘flexible’, ‘constantly changing’, ‘plural’, ‘reflexive’ and ‘diverse’ then these traits should be reflected in the institutions of education that serve society. The Department of Education (2002) has identified this trend by providing generic level descriptors that “can act as a starting point for curriculum planning and quality assurance for providers within and without formal education e.g. for employers offering work-based modules/unit standards”. The problem with this approach is aptly illustrated in the citation below:

Thus the university can no longer be identified by virtue of its separation from the outside world, while simultaneously big companies ... are becoming more conscious of their roles as creators, disseminators, and users of knowledge – a definition not altogether different from that of a university (Robins & Webster, 1999, p. 214).

The question that can consequently be asked is: What right does the university therefore have, above other sectors in society, to be the sole distributor of knowledge? Also, how will the university distinguish itself from other role-players such as industry? These questions are difficult to answer. Although Robins and Webster (1999) made a case for people to remain loyal to the university based on its sentimental ideals of “disinterestedness, critical inquiry, open debate, rigorous examination of evidence” (p. 217), this idea seems to be a rather emotional appeal to nostalgia; is it enough to ensure the future of the university in a rapidly changing society?

A more varied approach to categorising research

Research may, however, be even more varied than suggested by the dichotomous Mode 1 and Mode 2 debate presented above. As Muller (2000, p. 47) stated, “[i]t over-homogenises the evolution of a phenomenon that probably happened much earlier, and it over-dichotomises it, presenting it as two discrete ideal types that probably never exist in their pure form in the real world”. The various bodies governing higher education policy in South Africa have recognised the variation in approaches with their categorisation of research into four areas: traditional, applications-driven, strategic and participation-based, but clearly position these areas in Mode 2 learning.

The White Paper on Science and Technology: Preparing for the Twenty-First Century published by the Department of Arts, Culture, Science and Technology (DACST, 1996) “explicitly encourages problem-solving research through the formation of societal partnerships and cross-sectoral government policy co-ordination” (Kraak, 2000, 30). Robson (1993) also emphasised that research – or...
enquiry as he terms it - can be viewed as a way of solving problems. The difference, however, between the distinction of Mode 1 and Mode 2 knowledge production and the four areas identified by government on the one hand, and Robson’s perspective on the other hand, is that research is placed on a wider continuum. Solving problems ranges from purely theoretical to entirely practical as illustrated in figure 1. The dimensions also move from pure to applied research and according to increasing contribution from the client. No value judgement is attached to the dimensions; where a particular study lies on the continuum depends on the circumstances of an individual project.

Robson’s five dimensions do not adequately represent the characteristics of Mode 2 knowledge production as outlined in the previous section. A sixth dimension has therefore been added, namely the learning organisation. This portrays the type of research that takes place in a real world setting where the answer can be applied to a problem experienced by the organisation or other sectors of society. This is also referred to as a ‘networked’ mode of knowledge production, diversity within the organisation that “arises because Mode 2 is the outcome of teams of knowledge workers with diverse backgrounds, who in most cases are employed in pursuit of innovation by networking firms” (Kraak, 2000, p. 14). Muller (2000) would not place this type of research within the framework that has been provided above, as he views knowledge production of this kind as positioned outside of pure and applied research conventions. Similar to Kraak’s intended meaning cited above, Muller characterises the learning organisation as a place where interaction on a social level provides the necessary route to the kind of Mode 2 research described. To provide a clear picture to the reader of the contrasts and developments in the dimensions of research, however, the addition has been placed in figure 1.

Higher education and training institutions are thus faced with the challenges of engaging in the debate and positioning themselves in terms of Mode 1 and Mode 2 knowledge production. How these debates have been transformed into concrete measures to address the situation of South African education will be discussed in the following section.

### The effects of mode 2 learning on higher education policy and research in South Africa

Notwithstanding the reservations of certain academics and alternative views on the merits of Mode 2 learning, new higher education policies have been implemented (to lesser or greater degrees) in South African tertiary institutions. The South African government has recognised and integrated the trends of globalisation and massification in its policies affecting higher education. Indeed, Kraak (2000) identifies clear signs of Gibbons et al.’s (1994) and Scott’s (1995) work in the documents released by government, such as the National Commission on

Figure 1 Approaches to solving research problems
(Adapted from Robson, 1993)
Higher Education’s (NCHE) final report, A Framework for Transformation, released in 1996, the DoE’s Green Paper on Higher Education Transformation released in 1996, the Education White Paper 3: A Programme for the Transformation of Higher Education, also released by the DoE in 1997, and the 1997 Higher Education Act. Kraak (2000) categorises the NCHE report into five areas of recommendations regarding the transformation of higher education. These recommendations loosely overlap with the characteristics of Mode 2 learning institutions as set out briefly above. The implementation of the new policy in South African higher education would have certain consequences such as massification (by increasing student numbers and an increase in diversity in terms of the type of student and flexibility in the structure of how qualifications are presented), interdependence (by forming new relationships between tertiary institutions and key stakeholders in society), social accountability (by responding more actively to social and economic concerns), centralisation of planning (by putting a National Higher Education Plan in place to ensure a systematic approach to preparing South Africans for suitable roles in the global economy), preservation of institutional identity (by allowing institutions to initially retain their own identities and niche in the education market), providing programmes instead of courses and qualifications (by integrating and transforming isolated courses into broad programmes with a specific focus).

Besides the implications of new policy for higher education described above, an essential aspect of the recommendations for transformation that is relevant to this study deals with the changes that are touted by policy for research practice. The NCHE (1996) accepts the changing dynamic of knowledge creation, which encapsulates the themes of globalisation, massification, trans-disciplinarity, and the practical contribution of research to societal problems. The financial support made available for research projects also reflects these changes: “[f]unding is almost always from more than one source requiring different forms of interaction, accountability and management. Knowledge is increasingly trans-disciplinary and trans-institutional (a widened social base participating in its construction) ...” (NCHE, 1996, p. 126). Besides the new types of general skills that students must have to cope in the knowledge economy, under-graduate courses in research methodology should reflect the different way in which research is practiced in this environment. A module in research methodology will thus form part of and needs to fit into a broader programme. Students should be able to demonstrate certain skills on completion of a course that reflect the competencies they have acquired (Robins & Webster, 1999). More specifically, students should be equipped to secure funding (depending on the context they practice in) for research that is relevant and accountable, that is based on partnerships across various sectors of society and that makes use of different disciplinary fields.

Robins and Webster (1999) argued that this new context is driven by socio-economic imperatives which means that the structure and content of higher education will have to be linked to the requirements set by industry to train workers who will cope in this environment. As noted earlier, many of these features have made an appearance in documents released by government departments tasked with transforming the education sector in South Africa. For example, the NCHE (1996, p. 7) stated that “[h]igher education institutions will increasingly have to offer a greater mix of programmes, including those based on the development of vocationally-based competencies and skills needed in the workplace”. In particular, statements have been made about the role that (social science) research should play in achieving the government’s goals. The White Paper on Science and Technology released by the Department of Arts, Culture, Science and Technology (DACST, 1996) implies that the social sciences have not been making the kind of contribution that is necessary to effect the transformation in South African society that the government requires and that this should change. Tothill and Crothers (1997) asserted that this situation could be remedied by improving the class of education received by students, as future researchers, in the social sciences.

The assumption that can thus be articulated from the literature discussed above is that the curricula of under-graduate research courses at South African universities need to be re-examined in the light of the changing context of higher education in order to make suggestions about transformative actions that can be taken to improve the status quo, if necessary. One of the aims of this study is to examine how research courses have portrayed the policies of government in their curricula. Furthermore, any signs of the impact of the changing research environment will be sought. One of the ways in which to examine these two aspects is to explore the way in which academics that construct under-graduate research courses talk about the curriculum. The research question that this article considers is thus: How are the trends in Mode 2 requirements for higher education reflected in the beliefs held by academics that inform the way in which they think they should or should not construct under-graduate research courses?

METHOD

Research design

In order to explore the beliefs held by academics, a qualitative research design was chosen, as it would allow the researcher to hold in-depth, semi-structured conversations with participants to explore their talk about their curricula. In agreement with Polkinghorne (1983, p. 267), “the face-to-face encounter provides the richest data for the human science researcher seeking to understand human structures of experience”, and interviews are seen as the most intuitive way of uncovering meanings in this context. Approaching the people involved in under-graduate research courses provided a first-hand account of how they make sense of the curriculum and the factors that shape, maintain and transform it. Specific individuals were approached with the request to be interviewed about their methodology course(s). Although this study was driven from the discipline of psychology, all the social sciences were included as research methodology is a module that is germane to them. An interview guideline was developed based on the literature that was surveyed about the topic and the results from a larger study (Wagner, 2003) that mapped the content of under-graduate research courses. Semi-structured, in-depth interviews were conducted face-to-face with willing participants. Interviewees who were not in the Gauteng area received a similar interview guideline via e-mail.

Sample

Much care was taken to include a diverse range of participants in terms of their discipline, the type of course they teach (in terms of the categorisations developed from phase 1 which were: sparse courses (where the number of topics that are covered is small), pluralistic or charismatic (courses that convey many methods in social science research), qualitative-based (based solely on or emphasise topics commonly associated with qualitative research) and quantitative-based (where topics focus on quantitative methods or analysis of quantitative data)), geographical location (linked to the nine provinces in the country), institution in terms of training mode (distance, telematic or face-to-face interaction), language of instruction and categorisation in the previous education system.

Out of the 16 potential participants selected (plus a replacement sample of 10 individuals), nine were prepared to be interviewed face-to-face or returned their e-mailed questionnaires. Five females and four males took part in the
The interviewees were typically young or classified as junior staff members; only two people had doctorates at the time of the interviews. The race of the participants was as follows: one black person and eight white people. The interviews were mostly conducted with historically black universities.

Once the codes were established analytical emphases were chosen on which to base the meaning reconstruction. Carspecken (1996) noted that many criteria could serve to place emphasis on certain aspects of the codes, but that the validity of the emphasis should be foremost in the researcher's mind. The coding structure generated from the five steps above is still 'raw', according to Carspecken (1996), because no organisation of the codes has taken place. Redundancies and intersections between codes still exist and researchers need to pull these codes together. This forms the sixth step of the data analysis where researchers group certain codes and sub-codes together in categories. To facilitate the researcher's task of keeping an uncomplicated appearance in the presentation of the findings, those codes that formed part of a category were renumbered so that they followed a sequence from [01] to [...] across the categories. For example codes [01] to [03] were placed in the first belief category 'Under-graduate curricula should be developed by means of consensus', codes [04] to [05] were placed in the second belief category 'Under-graduate research methodology curricula should be constructed based on the expertise and research experience of academics' and so on. The eventual categories that the researcher formed from the interview data were based partly on suppositions made by the researcher from the findings in part one of the study, the focus of the study and discussions with her supervisor (as a form of peer debriefing). Nonetheless the researcher attempted to remain as close to the data as possible at all times.

The final part of the analysis, step seven, is to name and then flesh out each category to again ensure that the codes for the category fit the statements made by respondents or that a category is robust enough to stand on its own. The criteria that the researcher used to establish a belief category were derived from the interview data. For example codes [01] to [03] from the categories [04] to [05] across the categories. For example codes [01] to [03] were placed in the first belief category 'Under-graduate curricula should be developed by means of consensus', codes [04] to [05] were placed in the second belief category 'Under-graduate research methodology curricula should be constructed based on the expertise and research experience of academics' and so on. The eventual categories that the researcher formed from the interview data were based partly on suppositions made by the researcher from the findings in part one of the study, the focus of the study and discussions with her supervisor (as a form of peer debriefing). Nonetheless the researcher attempted to remain as close to the data as possible at all times.

Within the coding steps described above there are a further five steps that form the hermeneutic circle of interpretation. Due to space limitations the steps in this process are only listed as: virtual intersubjectivity, meaning-making through familiarity with the culture of the data, reflecting the researcher's norms, the normative circle and personal characteristics of research participants versus typical cultural behaviour. Detailed explanations of each of these steps can be found in Carspecken (1996).

The validity of the researchers' initial interpretation (thematic analysis) can be ascertained by assessing whether the participants agree with the statements that have been made (Carspecken, 1996). This is known as member validation and occurs at any stage of the analysis. The researcher engages with the participants about the process and includes the participants' views of the researcher's interpretation in the final analysis (Richardson, 1996). To perform a member check for the interpretation of the data in this study the themes that emerged from the interviews were sent to the participants and they were requested to send comments. This is a limited adaptation of member validation as the researcher did not engage in sustained dialogues with respondents, but it adheres to Gadamer's (1989) version of hermeneutics of alternating between an unfamiliar scheme and that of our own world. This may lead to the revision of our ideas and the eventual fusion of perspectives. Although researchers make their own interpretation of data this is one way of remaining open to improving one's reading of the phenomenon.
RESULTS

Three of the nine beliefs held by the respondents concerning the construction of under-graduate research methodology curricula, which relate to the focus of this article, are presented here. The categories are called beliefs because they hold the viewpoints of respondents on how and why the curriculum of their courses came into being.

Under-graduate research methodology courses should provide students with only a basic introduction to research versus students acquiring research skills

Many of the respondents made it clear that the under-graduate course they teach is only aimed at providing an introduction to research. Students learn useful background knowledge about research that can sometimes be implemented as skills in everyday life situations such as learning from your immediate environment by observing in it, knowing how to introduce yourself when entering situations and critical thinking skills. Some courses intentionally incorporate critical thinking and problem-solving skills in the curriculum, but according to the majority of respondents the courses do not claim to do more than impart knowledge. A few courses have specific outcomes in terms of skills such as enabling students to write a research proposal by the end of the course. The structure of the course is aimed at achieving this. For example “theory is not taught for the sake of it and all unnecessary technical methodological details have been thrown out”.

Under-graduate research methodology courses should prepare students for post-graduate research requirements

This belief is related to the supervision process of post-graduate students by constructors of under-graduate research courses. Two opposing beliefs were prevalent amongst the interviewees. The first belief is that knowledge of research is not meaningful for the contexts in which a discipline is practised; under-graduate research methodology is only useful to students who continue with post-graduate studies as it forms a basis for the research that students must conduct to attain a post-graduate qualification. Research skills are not seen as fundamental to the discipline, but rather something that can be contracted out to experts such as marketing research companies once the student has become part of a workplace. In one case the under-graduate curriculum was developed to focus only on quantitative research so that the post-graduate curriculum can deal with only the qualitative aspects that students use to complete their studies. These dissertations use mainly qualitative methods because it is believed that, in relation to quantitative methods, they more closely mirror the rest of the training that students receive in the substantive discipline. The second belief is that all professional persons do some degree of research in the execution of their duties, and thus skills in this field are necessary and integral to success in the workplace. For supervisors to forge and maintain relationships with industry, post-graduate dissertation topics should focus on the problems faced by industry and find solutions. Also, research methodology is seen as a skill that can provide students with extra tools to be able to perform at the level expected from them in the workplace.

What these two viewpoints seemed to have in common, however, is that the curriculum has been adjusted from a narrow focus to a broader one so that students receive training in the entire research process in order to feel comfortable when doing research on a post-graduate level. Academics thus believe that they should focus their attention on the needs and requirements of post-graduate qualifications to determine the content of the under-graduate curriculum.

Under-graduate research methodology courses should comply with the current educational framework

Some respondents believe that the current educational policy in South Africa should be taken seriously. The policy has impacted on the development of the research modules in that the new documentation was studied and principles of outcomes-based education were investigated so that academic programmes could be re-designed to build these principles into the courses. In the process most semester subjects were changed into modules. Two approaches were followed within the new dispensation: lecturers either integrated research components into specific modules or they designed research modules on their own. In some cases research methodology became a core module in certain programmes: “The course was designed in this way to allow students to have some knowledge even if they had to leave the programme and find employment in any field of research such as field workers, community facilitators etcetera.” Research modules were also rewritten to comply with policy.

Research methodology modules have also been reduced, in some cases, due to outcomes-based education and limited resources in terms of personnel. Structuring a programme according to OBE® principles results in a proliferation of new modules and, as departments want to include the core modules of a substantive discipline in programmes, research modules are cut. The reduction in space allocated for research has been managed in two ways. Firstly, as mentioned, research has been made an integral part of each module in a substantive discipline. In other words, research methodology does not stand on its own as a module, but forms part of the processes involved in community projects and the like. The second way of managing this problem is by reducing the content of research modules to ‘essential’ aspects, for example, concentrating on only quantitative methods.

Complying with national educational policy is viewed as a top-down approach where academics do not have much choice. A process is set in motion whereby senior members of staff attend meetings (the aim of the meetings is not always clear) and junior staff have to carry out any decisions made. This can lead to feelings of resentment. As one respondent puts it: “I think amongst academics there’s a certain sense of ‘we can function independently, we want to make our own decisions’ so I think academics are a bit unhappy about this, the top-down thing happening, but it’s always been like that but it seems to be more – how can I put it – enforced on another level almost”. A tension exists between being an independent academic and having to comply with the national education framework.

Although external forces influence the structure of courses, some academics view academia as allowing them a lot of freedom in terms of benefits such as the amount of vacation time, funding for involvement in departmental projects and attendance of international conferences. Nonetheless, the university as an institution is becoming more bureaucratic due to the increase in administrative duties that academic staff are experiencing, such as exercising more control over mark systems, attending many meetings and serving on committees. This creates a tension between the administrative and academic sides of curriculum development and teaching. One respondent believes that this situation originates with the top management of the institution and could also lie in the need to ease the workload of administrative staff.

DISCUSSION AND RECOMMENDATIONS

According to Tashakkori and Teddlie (2003), researchers in practice demand ‘research experts’ that are capable in using both qualitative and quantitative methods. The implication of this for higher education is that “those who teach research methodology in the social and behavioural sciences have a responsibility to prepare their students for a professional world that is increasingly using mixed methods” (Tashakkori &
Informing curriculum content: the demand of them. As social scientists they will be expected to have a first degree and depend on this qualification to graduate courses as the vast majority of students exit tertiary education at an undergraduate stage. The focus of this study is on undergraduate students for their possible future roles as post-graduates, their courses are constructed to address this belief and they train undergraduate students as future post-graduates, their courses are designed to prepare students for their future roles in research and/or promoted and/or respected professionally. It is the academic community of practice, students, academics, professionals and indeed anyone else who shares this site of practice, are responsible for the maintenance of the community of practice for inducting newcomers into it, for carrying on the tradition of the past and carrying the community forward to the future. Persons (students and staff) engage in legitimate peripheral participation in such communities of practice.

This may sound like the type of post-modern university and mode 2 research and teaching model that is described and criticised by Muller (2000) and Robins and Webster (1999). It should rather be viewed as the type of university that Habermas would advocate, where there is open dialogue amongst different parties and the best argument is accepted as the consensus viewpoint: “[t]he social norms of such an institution would not be those of mutually hostile isolationism but those of an open, self-reflective and innovative community, whose members share these values” (Blake, 1997, p. 163). Logistically this pathway may seem daunting, as one would need formal structures to ensure that enough time and space is provided for people to air their views. Brew (2003) concurs that this is a great challenge and that higher education has to be radically transformed to achieve this; however, she made some practical suggestions about how one may go about this. For example, graduate students could present some lectures, students could be rewarded by peers for their research work such as publishing articles in a student journal, and electronic formats for debates and conferences between students could be initiated. According to Brew, this also means that academics need to share power and be open to the challenges that they face such as negotiating what is accepted as knowledge and involving students in their research projects. It is thus proposed that the way forward for curriculum construction lies in establishing academic communities of practice that should be viewed as the type of university that Habermas would advocate: where academics need to share power and be open to the challenges that they face such as negotiating what is accepted as knowledge.

When research methodology is constructed and presented as an integrated course across disciplines in a faculty, positive spin-offs such as the sharing of resources and diversity of training takes place. From the interviews with lecturers, some of the negative consequences of adopting a Mode 2 approach are also evident. One respondent reported that the voices of smaller or non-co-operative departments are silenced. Departments that might make a meaningful contribution to a research course because of their particular field of expertise (Polkinghorne, 1992) are excluded because they have less power in the faculty and course construction is left to larger departments such as psychology and sociology. The way that marginalised departments deal with this situation is by creating organisational niches’ whereby they “bureaucratize knowledge by subject matter and stake a claim to research and train students in it” (Chubin, 1986, p. 4). In this way a department may see a certain research method as integral to their discipline and claim that they alone are experts on the topic and have the sole right to present related material. This may cause more conflict between disciplines and further marginalisation of small departments.

The suggestions that are made below arise from imperatives in the literature on higher education and research methodology teaching to revise our practices as academics in the way that we construct our curricula. Central to this is the belief that the kind of knowledge and the way in which we teach it needs to be legitimated in a broader arena and not only amongst ourselves (Barnett, 1997; McNair, 1997). A new model for achieving this purpose is proposed by Brew (2003, p. 12) who remarked that
