## Acknowledgements

---

My sincere gratitude goes to:

Prof DeWet Swanepoel, my promotor, for excellent and effective guidance. You guided with knowledge and wisdom, and your support was unfailing. You are a true mentor!

Dr Z Eloff, of Anglogold Ashanti, for trusting the data to me and for all the time spent talking through the study, also for two unforgettable journeys down the mine.

Prof Piet Becker, principle statistician at the Medical Research Council, for many, many hours spent making sense of this huge dataset. Your insight, patience and mathematical knowledge was invaluable to me.

Prof J W Hall for sharing your ideas and expert knowledge during your visits and also through email correspondence. It was a privilege to have you as a co-promotor.

Dr ACP Strauss for fast and effective language editing and constant encouragement.

Almero Strauss, for unfailing support, prayers and encouragement through tough times, and for many hours spent cleaning the data through your expert programming knowledge. Without you it would not have been possible!

My daughters Marianne, Annerine and Ameliè, your unconditional love and joy makes life an exciting and wonderful journey.

My parents for believing in me and encouraging me throughout my life.

My sister, Rachel Maritz, your daily reassurance and endless telephone calls inspired me.

Nico and Anita van der Merwe and my family at work; for trust, loyalty and support on many levels.

To Jesus Christ all the glory: Proverbs 2:6 : “For the Lord gives wisdom; from His mouth come knowledge and understanding.”

## Abstract

---

Despite the preventability of noise-induced hearing loss (NIHL) a high prevalence is still reported in South African mines. The study aimed to describe the hearing of gold miners pertaining to the prevalence and degree of NIHL and effectiveness of current RSA impairment criteria to identify NIHL.

The audiological data, collected between 2001 and 2008, of 57 714 mine workers were investigated in this retrospective cohort study. Data was accessed through the mine's electronic database and exported to Microsoft Excel 2007 worksheets. Participants were categorised in terms of noise exposure (level and working years), age, race and gender. Noise exposure levels were described in terms of a specific occupation and categorized into four groups based on dosimeter data received from the mine's noise hygienist, namely: 1) Below surface (underground) noise exposure,  $\geq 85$  dB A, classified according to the South African regulations on the daily permissible dose of noise exposure<sup>8</sup>, named Noise Group 1; 2) Surface noise exposure,  $\geq 85$  dB A, named Noise Group 2; 3) No known occupational noise exposure, named control group; and 4) Uncertain levels of noise exposure, e.g. students and trainees, named Noise Group 4. The control group was matched with participants of noise group 1 and 2 based on gender, race and age at the most recent audiogram test. Descriptive and inferential statistics were employed. Measures of central tendency and variability were used with analysis of covariance (ANCOVA) and pairwise comparisons according to Fisher's Least Squares Differences Approach (F test).

Results indicated that noise exposed groups had significantly higher prevalence of high and low frequency hearing loss than the control group. High-frequency hearing loss was also present in the control group. The greatest differences in prevalence of hearing loss were observed at 3, 4 kHz and age group 36 to 45 years. Thresholds at 8 kHz were worse than expected and decline slowed down with age. High-frequency thresholds showed a non-linear growth pattern with age with a greater decline at 2 kHz with age in the noise-exposed population compared to the control group. Hearing deteriorated more across age groups with more noise-exposed years, and this deterioration was most visible after 10 to 15 working years and at 3 kHz. Females had better hearing than males across the frequency spectrum. Black males

had significantly better high-frequency hearing than white males but significantly worse low-frequency hearing than white male counterparts. PLH values showed poor correlation (through statistical analyses) with other well-accepted hearing impairment criteria.

To date this was the largest study conducted on the hearing of gold miners and the sample included a very large number of black males exposed to occupational noise (N=17 933). Values supplied in distribution table format are therefore unique and contribute greatly to the knowledge base.

Table 5-17 Median threshold values across frequencies for female participants of the No Noise Group and Noise Group 1 categorised by age and compared to ISO 1990:1999 Annex B, as well as Hoffman, Dobie, Ko, Themann, & Murphy (2010)'s proposed new Annex B	147
Table 5-18 Median threshold values across frequencies for male participants of the administration group (admin) and driller group categorised by age and compared to ISO 1990:1999 Annex B, as well as Hoffman, Dobie, Ko, Themann, & Murphy (2010)'s proposed new Annex B	148
Table 5-19 Median threshold values across frequencies for male participants of the administration group (admin) and driller group categorised by age and compared to ISO 1990:1999 Annex B, as well as Hoffman, Dobie, Ko, Themann, & Murphy (2010)'s proposed new Annex B	149
Table 5-20 Median values for binaural average thresholds across the frequency range for white male participants of Noise Group 1 and the No Noise Group, compared to ANSI S3.44 (1996) Annex C	150
Table 5-21 Median values for binaural average thresholds across the frequency range for black male participants of Noise Group 1 and the No Noise Group categorised by age compared to ANSI S3.44 (1996) Annex C	151
Table 5-22 Median values for binaural average thresholds across the frequency range for black male participants of the driller and administration groups (admin) categorised by age compared to ANSI S3.44 (1996) Annex C	152

*Table 5-23 Median values for binaural average thresholds across the frequency range for white male participants of the administration (admin) and driller groups categorised by age compared to ANSI S3.44 (1996) Annex C..... 153*

*Table 6-1 Prevalence data from the current study compared to data from the Girard et al. (2009) study, categorised into ISO (1990) age categories and Yantis (1994) hearing loss categories, HFA346 used to define hearing loss. .... 171*

*Table 6-2 Noise Group 1: Number and percentage of participants in each age group (ISO 1990) for each hearing loss category (Yantis, 1994), combined percentages for hearing loss greater than 30 dB HL and percentage values of Hessel & Sluis-Cremer (1987) participants with PTA512 values greater than 25 dB HL..... 175*

## List of Acronyms

---

AMA	American Medical Association
ANSI	American National Standards
ARHL	Age related hearing loss
ASHA	American Speech and Hearing Association
COIDA	Compensation for Occupational Injuries and Diseases Act, No. 130 of 1993. South Africa
dB A	Decibel A-weighted
dB HL	Decibel hearing level
dB SPL	Decibel sound pressure level
DPOAE	Distortion Product Otoacoustic Emission
HCP	Hearing conservation programme
HEG	Homogenous exposure group
ISO	International Organization for Standardization
kHz	Kilohertz
MHSC	Mine Health and Safety Council
NIHL	Noise-induced hearing loss
NIOSH	US National Institute for Occupational Safety and Health
OAE	Otoacoustic Emission
OEL	Occupational exposure level
OSHA	The United States Occupational Safety and Health Administration
PLH	Percentage loss of hearing
PTA346	Pure tone average of 3, 4 and 6 kHz
PTA512	Pure tone average of 0.5, 1 and 2 kHz
RSA	Republic of South Africa
SANS	South African National Standards
SANS 10083: 2007	SANS: The measurement and assessment of occupational noise for hearing conservation purposes
TWA	Time weighted average
WHO	World Health Organization
