## Abstract

Ecological restoration has the potential to stem the tide of habitat loss, fragmentation and transformation that are the main threats to global biological diversity and ecosystem services. Through this thesis, I aimed to evaluate the ecological consequences of a 33 year old rehabilitation programme for coastal dune forest conservation. The mining company Richards Bay Minerals (RBM) initiated what is now the longest running rehabilitation programme in South Africa in 1977. Management of the rehabilitation process is founded upon the principles of ecological succession after ameliorating the mine tailings to accelerate initial colonisation.

Many factors may detract from the predictability of the ecological succession. For example, if historical contingency is a reality, then the goal of restoring a particular habitat to its former state may be unattainable as a number of alternative stable states can result from the order by which species establish. Succession appears to be a suitable conceptual basis (at this stage in regeneration at least) for the restoration of coastal dune forest. Patterns of community characteristics observed in rehabilitating coastal dune forest sites were similar to those predicted by ecological succession, with few exceptions.

Changes in the species pool such as the establishment of strong dominants may lead to divergence of regenerating trajectories away from the desired endpoints. The species composition of herbaceous plants in regenerating coastal dune forest sites became increasingly uniform as the time since disturbance increased. Despite initially becoming more similar they

deviated away from an undisturbed reference site. Contrary to our expectations, non-native species did not contribute the most to dissimilarity. The deviation from the reference forest is attributable to the higher abundance of a native forest specialist in the reference site and the higher abundances of native woodland adapted species in the rehabilitating sites.

Changes in the disturbance regime under which species have evolved may lead to arrested succession. The rehabilitation of coastal dune forest relies on the *Acacia karroo* successional pathway which, has been criticised because *Acacia* dominated woodlands may stagnate succession. The patterns of species composition within regenerating coastal dune forest are a response to the canopy characteristics and represent an early stage in forest succession. Succession did not appear to be stagnant.

Ecological succession does not pay much heed to the role that the surrounding landscape composition can play in the assembly of communities. The theory of Island biogeography provides predictions about how landscape composition influences community assembly. Landscape spatial parameters, measuring edge, isolation, and area explained the patch occupancy of the several bird and tree species, however, responses to patch characteristics were varied and idiosyncratic. For restoration to succeed, managers need to consider the spatial configuration of the landscape to facilitate colonization of rehabilitating patches.

From this thesis and previous work, it appears that processes are in place that will lead to the reassembly of dune forest communities. As the rehabilitating sites are at an early stage of regeneration this may take some time to give rise to these coastal dune forest communities, and the management of rehabilitating coastal dune forest must allow for this. In addition, it is

important to remember that time may be interacting with the landscapes spatial attributes, which may limit the presence of certain species.

## Acknowledgements

I could not have written this PhD thesis without the assistance of many people. First, I wish to thank my supervisor, Professor Rudi van Aarde. His dedication, passion for the project and tutorage has been invaluable to not only the development of this thesis, but also my own development as a scientist. He believed in my abilities even when I doubted them myself. Thank you Prof.

Dr. Theo Wassenaar was integral to the development of this thesis and his advice and assurance has been crucial to the completion of this thesis. Theo taught me many things, not least the difference between the words “effect” and “affect”. Baie dankie, Theo!

My fellow members of the CERU family have been a great support network, providing discussions on theoretical conundrums, advice on methodological approaches to problems, proof-reading of manuscripts and of course a group of friends to have beer with once in a while. I wish to thank Dr. Robert Guldemon, Jo Fourie, Morgan Trimble, Pieter Olivier, Carrie Roever, Cornelio Ntumi, Alida de Flamingh, Tamara Lee, and Kim Young. Theresia Ott has additionally offered assistance and advice with GIS for which I am very grateful. Lilian Scholtz assisted in administration and provided a battering ram to bureaucracy. Adrian Haagner, Antoinette van Wyk, James Sibiya and Thabile Khuzwayo assisted me in orientating myself in my study site, and in carrying out fieldwork.

I wish to pay special thanks Michelle Boshoff from RBM who facilitated my research on the mining lease. Michelle’s enthusiasm for the conservation of South Africa’s biological diversity is infectious. In addition, without Michelle’s friendship life in Richards Bay would

have been much impoverished. Richards Bay Minerals and the University of Pretoria provided both logistical and financial assistance for which I am extremely grateful.

Finally, I wish to say thank you to my family for the support they have given me. My South African “family”, the Martyns’, provided a home away from home and support that made my life in Richards Bay very enjoyable. I do not have the words to express the gratitude that I have for the most important person in my life, Laura Owens. She has stood by me throughout what I suspect she has viewed as an ordeal! I appreciate her unending support and belief in me.

## Disclaimer

The present dissertation includes four paper manuscripts, prepared for submission to different scientific peer-reviewed journals. Styles and formatting of these chapters follow the respective journal requirements. This results in some duplication in the study site description and methods between chapters. Chapters 3, 4, and 6 follow the format requirements for the journal *Restoration Ecology*, whereby Chapter 5 follows the requirements for the *Journal of Vegetation Science*. Chapter 6 has already been published in *Restoration Ecology* as “Grainger, M.J., R.J. van Aarde and T.D. Wassenaar (2011). Landscape Composition Influences the Restoration of Subtropical Coastal Dune Forest. *Restoration Ecology* **19**: 111 – 120 (DOI: 10.1111/j.1526-100X.2009.00630.x)”. I hereby declare all the work to be my own and that I have acknowledged all those that helped me and contributed to producing this dissertation.

## List of Tables

Table 2-1. The tree species recorded in the Sokhulu Forest and Mapelane Nature Reserve between 1997 and 2005.....39

Table 2-2. The herbaceous plant species recorded in the Sokhulu Forest and Mapelane Nature Reserve in 2005.....43

Table 2-3. Bird species recorded in the Sokhulu Forest and Mapelane Nature Reserves between 1997 and 2009.....46

Table 2-4. Millipede species recorded in the Sokhulu Forest and Mapelane Nature Reserves between 1997 and 2009.....50

Table 3-1. Trends expected in structural and functional community characteristics of regenerating sites undergoing ecological succession.....82

Table 3-2. Survey years and site ages for each rehabilitating coastal dune forest site, indicated by the year of establishment 1977 to 2003. Surveys for herbaceous plants, millipedes, birds, trees and soil took place in different survey years.....84

Table 3-3. The slope of the regression lines for species richness, diversity and evenness for herbaceous plants, trees, millipedes and birds. The randomized chronosequence is the expected trend and the individual sites the observed trend.....85

Table 4-1. Results of a SIMPER analysis showing the 10 species with the highest contribution to Bray Curtis dissimilarity between each age category and the undisturbed Sokhulu forest.....119

Table 5-1. A summary of our assumptions and expectations.....144

Table 5-2. Gap characteristics in three regenerating coastal dune forest sites.....145

Table 5-3. Differences in the abundance of each species in canopy gaps and intact canopy, as well as in each canopy gap size class (Small, Medium, Large or Very Large) for the three size classes (Adult, Sapling and Seedlings).....146

Table 5-4. Reported gap proportion and gap area from a variety of forest types, “N/A” indicates where information was not available.....148

Table 6-1. The number of species whose patch occupancy was best explained by each model, the numbers in brackets indicate the number of species that have each model as a plausible alternative.....177

Table 6-2. Results of model selection for 25 forest associated tree species and 21 forest associated bird species. The variables included in the model selection include patch age (1), patch area (2), distance from Sokhulu (3), and patch shape index (4).....178

## List of Plates

Plate 1-1. Mining operations at Richards Bay Minerals result in the removal of all vegetation and topsoil in front of the mining pond. Topsoil is stockpiled for use on rehabilitating sites. Immediately post-mining sand is formulated in to an approximation of the dunes previous topography. The photograph was taken by Prof. R.J. van Aarde and is used with permission....16

Plate 1-2. This plate shows a rehabilitating site at less than 1 year old. Topsoil stockpiled prior to mining is replaced on re-shaped dunes and wind-breaking fences erected to limit soil erosion. The soil is seeded with exotic annual seeds that provide a cover crop, further stabilising the soil. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....17

Plate 1-3. This rehabilitating site is around 1 year old. Here the dune has a layer of topsoil and wind-breaking fences have been erected. In the foreground, a cover crop of exotic annual herbaceous plants has established. In the background, there are active mining operations, adjacent to previously rehabilitated coastal dune forest.....18

Plate 1-4. This rehabilitating site is around 3 years old. Various graminoids have established alongside the pioneer tree species *Acacia karroo*, which is shown in the foreground. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....19

Plate 1-5. This ~8 year old site is dominated by *A. karroo*, with a developing herbaceous layer. Self-thinning of *A. karroo* potentially allows secondary species to colonise the site. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....20

Plate 1-6. At ~28 years old, *A. karroo* is still the dominant canopy tree species. However several forest-associated species have established in the site, and there is a developed herbaceous layer. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....21

Plate 1-7. At ~32 years old, individuals of *A. karroo* are beginning to reach senescence and the death and subsequent collapse of these canopy individuals may allow broadleaved secondary species to replace them in the canopy. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....22

Plate 7-1. Post-mining dunes are re-shaped and then previously stored topsoil is placed on the dune and spread evenly across the site. The erection of shade-netting fences, acts to reduce soil erosion resulting from the action of the wind. Exotic annual herbaceous plants are seeded to further ensure soil stability. The above plate shows a 1 year old site. The photograph was taken by Prof. R.J. van Aarde and is used with permission.....240

## List of Appendices

Appendix 3-1. Herb species and their Non-metric Multidimensional Scaling (NMDS) scores for axis 1 to 3 and their habitat associations according to Pooley (1998). Species are listed in order of their NMDS axis 1 score.....248

Appendix 3-2. Bird species, their Non-metric Multidimensional Scaling (NMDS) scores for axis 1 to 3 and their habitat associations according to Gibbon (2006).....255

Appendix 3-3. Tree species, their Non-metric Multidimensional Scaling (NMDS) scores for axis 1 to 3 and their habitat associations according to Coates-Palgrave (2003).....258

Appendix 3-4. Millipede species and their Non-metric Multidimensional Scaling (NMDS) scores for axis 1 to 3. There are no independent sources of information on their habitat associations..261

Appendix 4-1. The year of establishment and mean elevation (meters above sea level) for each rehabilitating coastal dune forest site.....262

Appendix 4-2. The 15 non-native species recorded in the rehabilitating coastal dune forests. All species listed in the Conservation of Agricultural Resources Act (1983) are in category 1; species that are prohibited weeds in need of control in all situations. Species authorities are sourced from the International Plant Names Index (<http://www.ipni.org/index.html>).....263
