

## CHAPTER 5

### Polyphasic Characterisation of *Pantoea* Strains from Onion and Maize, and the Description of *Pantoea allii* sp. nov.

#### Abstract

Bacteria from the genus *Pantoea* have become increasingly important plant pathogens around the world. In South Africa, they cause diseases of two economically important crops, *Eucalyptus* and maize. The strains inducing center rot of onion have only been found in onion seed in this country, and have not yet been associated with any disease outbreak. The identity and taxonomic position of *Pantoea* isolates from onion and maize has not been fully determined. Forty-seven strains were subjected to a polyphasic study that included phenotypic characterisation, analysis of the F-AFLP patterns, rep-PCR genomic fingerprinting, 16S rDNA gene sequences and DNA-DNA hybridisation. The results revealed that the strains belong to three different species within the genus *Pantoea*. Majority of strains were identified as *P. ananatis*. Indole-negative strains from maize were identified as *P. vagans*. Some strains from onion, previously classified as *P. ananatis*, were shown to form a novel species. The name *Pantoea allii* sp. nov. is proposed for these strains (type strain BD 390<sup>T</sup>) and the description of the species is presented.

## INTRODUCTION

Bacteria belonging to the genus *Pantoea* are common on plant surfaces, in seeds, soil, and water and have been isolated from humans and animals (Gavini et al., 1989; Mergaert et al., 1993). Many microbiologists have studied the taxonomy of the genus. The studies included the numerical analysis of phenotypic characteristics (Verdonck et al., 1987), 16S rRNA gene sequence analysis (Hauben et al., 1998), fatty acid and protein profile analyses, DNA-DNA hybridisation (Brenner et al., 1984; Beji et al., 1988; Gavini et al., 1989, Mergaert et al., 1993) and AFLP fingerprints analysis (Brady, 2005). There are seven described species within the genus *Pantoea*: *P. agglomerans*, *P. ananatis*, *P. citrea*, *P. dispersa*, *P. punctata*, *P. terrea*, and *P. stewartii* containing two subspecies, *indologenes* and *stewartii*. There are also several hybridisation groups from a study by Brenner et al. (1984), and a protein profile group of Beji et al. (1988), that according to the latest edition of the Bergey's manual of systematic bacteriology belong to the genus *Pantoea* (Grimont and Grimont, 2005).

Plant pathogenic *Pantoea* species cause diseases on diverse crops, such as pineapple (Serrano, 1928; Kageyama et al., 1992), melons (Bruton et al., 1986; Wells et al., 1987), cantaloupe (Bruton et al., 1991) sudangrass (Azad et al., 2000), *Eucalyptus* (Coutinho et al., 2002), rice (Azegami et al., 1983; Cother et al., 2004), mandarin orange (Kageyama et al., 1992), sugarcane (Serrano, 1928), beets (Brown, 1928), *Gypsophila* (Brown, 1934), onion (Hattingh and Walters, 1981; Gitaitis and Gay, 1997; Schwartz and Otto, 2000; Goszczynska et al., 2006) and maize (Elliott, 1941; Paccola-Meirelles et al., 2001; Goszczynska et al., 2007). Disease symptoms are diverse and include galls, rots, wilt, leaf blights, necrosis and spots, dieback and stem necrosis (Grimont and Grimont, 2005).

However, not all *Pantoea* strains are plant pathogens, and some have been used for biological control of *Erwinia amylovora* (Beer et al., 1984) and *Xanthomonas albilineans* (Zhang and Birch, 1997). Some strains of *P. agglomerans* (Nunes et al., 2001) and *P. ananatis* (Torres et al., 2005) are effective for the biological control of post harvest pome fruit diseases caused by fungi.

Diseases of onion are characterised by leaf blight, central leaf rot, seed stalk necrosis and rot, and bulb decay and these symptoms can lead to economically significant losses (Hattingh and Walters, 1981; Walcott et al., 2002). These diseases are caused by *P. ananatis* (Gitaitis and Gay, 1997) and *P. agglomerans* (Hattingh and Walters, 1981). The strains of *P. ananatis*

inducing center rot of onion have only been found in onion seed in South Africa, and have not yet been associated with any disease outbreak (Gosczynska et al., 2006).

Brown stalk rot of maize was first observed in South Africa in 2004 and was caused by *P. ananatis* and an unknown *Pantoea* sp. similar phenotypically to *P. agglomerans* (Gosczynska et al., 2007). Affected plants were stunted, with a vertical crack at the first internode, surrounded by a dark brown, narrow lesion. Internal browning inside the stem extended upwards, reaching the top internode in some plants. Seed cobs were underdeveloped. Diseased plants were scattered over the fields and 10-70% of the crop was affected (Gosczynska et al., 2007).

The diseases of onion and maize caused by *Pantoea* species were recorded for the first time during the last decade. Their taxonomic position has not been fully clarified. Bacteria isolated from onion in the USA and South Africa was considered to be *P. ananatis*. This classification was based only on biochemical and physiological characteristics (Gitaitis and Gay, 1997; Schwartz and Otto, 2000; Walcott et al., 2002) and the analysis of the 16S rDNA sequences (Gosczynska et al., 2006). Such methods are often insufficient for species delineation according to the recommendation of Wayne et al. (1987) and Stackebrandt et al. (2002). *Pantoea* strains isolated from maize with brown stalk rot symptoms in South Africa were additionally examined by using fluorescent amplified fragment length polymorphism analysis (F-AFLP) (Gosczynska et al., 2007). The majority of strains isolated from diseased maize were *P. ananatis*. Several isolates, although similar to *P. agglomerans* on the basis on biochemical tests and 16S rDNA sequences, produced F-AFLP fingerprints that were distinctly different from that generated by *P. ananatis*, *P. agglomerans*, *P. dispersa*, *P. citrea*, *P. stewartii* subsp. *stewartii* and *P. stewartii* subsp. *indologenes*. The results indicated that these bacteria belong to a previously undescribed species of the genus *Pantoea* and their taxonomic status needed to be further investigated. Bacteria recently isolated from *Eucalyptus* in Uganda were proposed to form a new species within a genus *Pantoea*, *P. vagens* (unpublished results(Gosczynska et al., 2007)). The type strain of *P. vagens*, BCC 105<sup>T</sup> was included in this study.

The present research was initiated to characterise a collection of *Pantoea* strains from onion and maize by a polyphasic approach based on analyses of carbon source utilisation,

physiological characteristics, 16S rRNA gene sequence analysis, DNA-DNA hybridisation and F-AFLP. Based on the results obtained, the new species *Pantoea allii* is proposed.

## MATERIALS AND METHODS

**Bacterial strains.** Sixty-seven bacterial strains used in the study are listed in Table 1. Twenty-four strains were originally isolated from onion plants and seed in the USA and South Africa. Twenty-three strains were isolated from maize with brown stalk rot in South Africa. Twenty *Pantoea* strains, including the type strains of *P. ananatis*, *P. agglomerans*, *P. citrea*, *P. dispersa*, *P. vagans*, *P. stewartii* subsp. *indologenes* and *P. stewartii* subsp. *stewartii* were used as reference strains. The strains were routinely cultured on tryptone glucose extract agar (TGA) (Difco, Sparks, MD), at 26°C and preserved in milk glycerol liquid medium (10% skim milk, 15% glycerol in distilled water) at -20°C. All cultures were routinely checked for purity and colony characteristics on TGA.

**Pathogenicity tests.** Pathogenicity on onion cv. Granex 33 was determined in green house assays by using a stub inoculation test (Goszczynska et al., 2006). A sterile needle was dipped into the bacterial colony on TGA (24-48 hours growth) and then the needle was inserted under the epidermis of a leaf. At least two leaves were inoculated per isolate. Inoculated plants were incubated in a greenhouse with 27°C/23°C day/night temperatures and observed daily for the development of symptoms.

Pathogenicity on maize was determined in greenhouse assays on a susceptible maize cultivar SR 52 (Goszczynska et al., 2007). Nine-week-old plants were inoculated by injecting a few drops of bacterial suspensions into the first internode of the stem. Maize plants were maintained in a greenhouse with natural light and at temperatures and RH described above. At least two plants were inoculated with each bacterial strain per inoculation method. This experiment continued for ten weeks.

Three control plants in all experiments were inoculated with sterile distilled water.

## Phenotypic methods

**Morphological and physiological characteristics.** Strains from onion and maize were characterised by colony morphology, pigment production on TGA, motility, cell

morphology, Gram-stain, oxidase reaction, catalase reaction, indole production, Hugh-Leifson oxidation/fermentation test, gas production from glucose, hydrogen sulphide production from cysteine, growth at different temperatures (4, 30, 37, 40 and 44°C), and tolerance to NaCl (Mergaert *et al.*, 1993). The tests were performed according to methods described by Fahy and Hayward (1983).

**Utilisation of carbon sources.** All strains listed in Table 1 were characterised phenotypically by the Biolog GN2 microplate system (Biolog, Inc., Hayward, CA), according to the manufacturer's instructions. The inoculated microplates were incubated at 30°C for 24 hours. Plates were then scored visually for carbon source utilisation patterns. The data was entered into the Bionumerics software (version 4.5, Applied Maths, Kortrijk, Belgium). Similarity matrixes were constructed using the Pearson coefficient. Groups of strains were defined by the unweighted pair group method (UPGMA) using the same software.

**Biochemical tests.** Biochemical characteristics of the strains listed in Table 1 were examined with the API 20E system (BioMérieux, La Balme les Grottes, Montalieu Vercieu, France), according to the procedure recommended by the manufacturers. Selected strains were also tested with the API 50CHE system. The results of the API 20E and API 50CHE tests were recorded after 24 and 48 hours of incubation at 30°C respectively.

Two cluster analyses were performed using the Bionumerics software. The first analysis was done with the API 20E data (21 characters) for all strains listed in Table 1 and the second analysis with the API 50CHE (49 characters) data for selected strains. Similarity matrixes were constructed with the Dice coefficient and cluster analyses were performed by the UPGMA method. The data was presented as UPGMA dendograms.

## Molecular methods

**DNA extraction.** Genomic DNA of bacterial strains (Table 1) was extracted by using the GenElute Bacterial Genomic DNA Kit (Sigma, Steinheim, Germany), according to the manufacturer's instructions. Purified DNA was quantified using a Dyna Quant 200 fluorometer (Hoefer, San Francisco, CA) and Hoescht H 33258 intercalating dye (Polysciences, Warrington, PA). The DNA was stored at -20°C until further analysis.

**Fluorescent amplified fragment length polymorphism (F-AFLP).** All strains listed in Table 1 were examined by the fluorescent amplified fragment length polymorphism (F-AFLP)-based system for the identification of plant-associated species from the genus *Pantoea*, as described by Brady et al. (2006).

Genomic DNA, 50-100 ng from each isolate, was digested with *Eco*RI and *Mse*I (Roche, Mannheim, Germany) restriction enzymes, and then ligated to the respective adaptors. Pre-amplification PCR reactions were done with Eco-00 (5'-GAC TGC GTA CCA ATT C-3') and Mse-00 (5'-GAT GAG TCC TGA CTA A-3') primers. Selective PCR amplifications were performed with Mse-CG (5'-GAT GAG TCC TGA CTA ACG-3') and fluorescently labelled Eco-G (5'-GAC TGC GTA CCA ATT CG-3') primers. Amplifications were done at least twice for each strain in the Hybaid Omni Gene thermocycler (Teddington, England) according to the Brady (2005) specifications.

The selective amplification reactions (1 µl) were mixed with an equal volume of formamide loading buffer (95% formamide, 20 mM EDTA, bromophenol blue), heated for 3 min at 90°C and then chilled on ice for 10 min. A volume of 0.5-0.8 µl of each mixture was loaded onto the gel. The AFLP products were separated in 8% Long Ranger (LI-COR Biosciences, Lincoln, NE) denaturing gels on a LI-COR IR automated sequencer. Electrophoresis was carried out for 4 hours at 1500 V in 0.8 x TBE buffer. Images were imported into BioNumerics software. Gels were standardized with a 50-700 bp sizing standard (LI-COR) and the bands between 50 and 700 bp were analysed (Brady, 2005).

Similarity of the AFLP fingerprints was calculated using the Dice correlation coefficient and the cluster analysis was performed using the unweighted pair group method (UPGMA). The results were presented as an UPGMA dendrogram.

**Repetitive sequence based PCR genomic fingerprinting.** Repetitive sequence based polymerase chain reaction (rep-PCR) genomic fingerprints were obtained for all strains listed in Table 1. PCR was performed in 10 µl volumes containing PCR buffer (10 mM Tris HCl, pH 9.0 at 25°C; 50 mM KCl; 0.1% Triton X-100); 3.5 mM MgCl<sub>2</sub>; 150 µM dNTPs; 1.0 µM primer, 2.5% DMSO; Taq polymerase (Promega, Madison, WI) 0.15 units per reaction volume and 25-50 ng template µl<sup>-1</sup>. Primers used in the PCR corresponded to the prokaryotic enterobacterial repetitive intergenic consensus (ERIC2) and the BOX1A subunit of the BOX element (Rademaker and de Bruijn, 1997). PCR reaction volumes were overlaid with 10 µl sterile mineral oil and PCR amplifications performed according to Rademaker and de Bruijn (1997) in a Hybaid Omni Gene thermocycler.

The rep-PCR products were separated in 1.5% agarose in 1 x TBE buffer at 80 V. Gels were stained in ethidium bromide (10 mg ml<sup>-1</sup>) for 10 min and destained for 15 min in water. Images were imported into BioNumerics software. The similarity between strains was calculated using the Pearson's correlation coefficient applied to the entire densitometric curves of the gel tracks. Gels were standardized with DNA molecular weight marker VI (Roche, Steinheim, Germany). All PCR reactions were repeated at least twice. Cluster analysis was performed by the UPGMA method and the data presented as an UPGMA dendrogram.

**16S rRNA gene sequence analysis.** The 16S rRNA gene fragments of nine strains from onion and twelve strains from maize were amplified in previous studies (Goszczynska et al., 2006 and 2007). The GenBank accession numbers (National Center for Biotechnology Information, U.S. National Institute of Health, Bethesda, MD) are shown in Fig. 4. Ilse Cleenwerck (Ghent University, Belgium) provided the 16S rDNA sequences of *P. citrea*, *P. punctata* and *P. terrea*. Carrie Brady (University of Pretoria) supplied the sequence of *P. vagans* BD 105<sup>T</sup>.

The 16S rDNA nucleotide sequences of strains from maize and onion were aligned with a selection of 16S rDNA sequences of *Pantoea* species from GenBank with the MAFFT software, ver. 5.743 (Katoh et al., 2002). Phylogenetic trees were constructed with the neighbor joining method (Saitou and Nei, 1987) and evolutionary distances calculated

according to the method of Kimura (1980), using the MEGA software package, version 3.1, Kumar, Tamura, Nei, 2004 (Kumar et al., 2004). Bootstrap analysis of the data, based on 1000 permutations was used to assess the stability of relationships.

**DNA-DNA hybridisation.** The DNA was extracted from the five strains from onion (BD 309, BD 310, BD 377, BD 390, PA 4) three strains from maize (BD 435, BD 442, BD 639), BCC 105 from *Eucalyptus*, and the type strains of *P. ananatis* LMG 2665<sup>T</sup>, *P. agglomerans* LMG 1286<sup>T</sup>, *P. stewartii* subsp. *stewartii* LMG 2715<sup>T</sup>, *P. dispersa* LMG 2603<sup>T</sup> and *P. vagans* BCC 105<sup>T</sup>, using the method described by Wilson (1989) and modified by Cleenwerck et al (2002).

DNA-DNA hybridisations were performed with photo-biotin-labelled probes in microplate wells (Ezaki et al., 1989; Goris et al., 1998) as described by Cleenwerk et al. (2002). Fluorescent measurements were done with a HTS7000 BioAssay Reader (Perkin-Elmer Cetus, Norwalk, CT). The hybridisation temperature was 45°C. Reciprocal experiments were performed for every pair of strains, and the means from reciprocal tests were presented.

## RESULTS

**Pathogenicity tests.** All *Pantoea* strains isolated from onion induced identical symptoms on onion leaves cv. Granex 33 in pathogenicity tests. Two to four days after inoculation water soaked spots appeared on leaves that expanded into longitudinal, bleached-green lesions with chlorotic margins (Fig. 1).

All *Pantoea* from maize produced brown stalk rot symptoms within six to seven weeks (Fig. 2). Four to six days after inoculation, small, 2-4 mm, light brown or dark green lesions developed around the inoculation point. Additionally, drops of yellow liquid slowly oozed from the lesion for two to three days. After 6 to 7 weeks, a single, long, vertical crack appeared on the injected internode. A dark brown, narrow lesion was present in the internal stem tissue along the crack. The internal browning within the stem was also observed in upper internodes.

**Morphological and physiological characteristics.** The strains from onion and maize produced yellow colonies on TGA, were gram-negative rods (1.5-2.0 µm length and 0.5-0.75

µm width), motile, oxidase negative and catalase positive. All strains fermentatively utilised glucose. They did not produce gas from glucose nor hydrogen sulphide from cysteine. Majority of strains produced indole from tryptophane, with the exception of *Pantoea* sp. from maize. Cells grew on nutrient agar containing up to 6% NaCl.

*Pantoea* strains should be classified and identified mainly based on genotypic characteristics, as identification based on phenotypic tests does not always lead to clear results (Gavini et al., 1989, Mergaert et al., 1993). Thus, the results of molecular characterisation of the strains from onion and maize are presented first, followed by the phenotypic description.

### Molecular characterisation

**F-AFLP analysis.** *Pantoea* strains used in the study generated complex DNA fingerprints from extracted genomic DNA (Fig. 3). The selective primers Eco-G/Mse-CG (Brady, 2005) yielded well-defined DNA fingerprints, with an average of 80 bands per isolate. Amplified DNA fragments ranged in size from approximately 50 bp to slightly greater than 700 bp. A total of 101 fragments were generated and all these fragments were polymorphic. Sixty-seven *Pantoea* strains formed seven clusters. Majority of strains from onion and maize clustered with *P. ananatis* type strain LMG 2665<sup>T</sup> and *P. ananatis* reference strains. The similarity values among these strains were between 73 and 98%.

The strains from maize, classified as *Pantoea* sp. in a previous study (Goszczynska et al., 2006), formed a cluster with *P. vagans* BCC 105<sup>T</sup>. The F-AFLP fingerprints obtained for these strains showed 87 to 94% similarity.

Five strains from onion, indistinguishable from *P. ananatis* by biochemical and morphological characteristics, generated F-AFLP patterns that were clearly different from those produced by other isolates used in the study, including the type strains of *P. ananatis*, *P. agglomerans*, *P. citrea*, *P. dispersa*, *P. vagans*, *P. stewartii* subsp. *stewartii* and *P. stewartii* subsp. *indologenes*. Fingerprints of BD 304, BD 309, BD 377, BD 380 and BD 390 were 70 to 92% similar to each other.

**Rep-PCR genomic fingerprinting.** The rep-PCR fragments amplified with the BOX1A and ERIC2 primers, ranged in size from approximately 230 bp to greater than 3 kb. The banding

pattern revealed a high degree of genetic diversity among the strains. Although significant differences were observed between the major groups, within each group of strains fingerprints were similar (Fig. 4). The groups of strains obtained by the analysis of the rep-PCR data were identical to that obtained by using the F-AFLP fingerprints.

The DNA fingerprint similarity among most of isolates from onion, maize, and *P. ananatis* reference strains ranged from 50% to 99% and all these strains clustered together on the rep-PCR dendrogram. The indole-negative strains from maize (Gosczynska et al., 2007) produced characteristic and unique rep-PCR fingerprints. BD 502 and BD 639 formed a separate cluster on the dendrogram with the type strain of *P. vagans*.

A group of five strains from onion (BD 304, BD 309, BD 377, BD 380 and BD 390), generated rep-PCR fingerprints that were similar to each other (50 to 80%), but distinctly different from other strains. The same five isolates also grouped together on the F-AFLP dendrogram.

**16S rRNA gene sequence analysis.** Figure 5 shows the phylogenetic relationship derived from a neighbor-joining analysis of the pairwise comparison among the 16S rDNA sequences of twelve strains from maize and nine strains from onion. The 16S rDNA sequences of fourteen *Pantoea* reference strains, including the type strains of seven described species within the genus were included in the analysis. The multiple sequence alignment of thirty-five 16S rDNA sequences used in the study is presented in Appendix A.

Phylogenetic evaluation confirmed the division of strains from maize and onion into three groups. Nine maize and five onion strains, that produced genomic fingerprints similar to *P. ananatis*, clustered with the 16S rDNA sequences of *P. ananatis*. Two indole negative isolates from maize grouped closely, at 62% confidence value, with *P. vagans* BCC 105<sup>T</sup>. Although the sequences of three onion isolates, BD 309, BD 377 and BD 390 were more than 99% similar to that of *P. ananatis*, they formed a separate cluster in the tree, at a high, 81% confidence value.

**DNA-DNA hybridisation.** Between two and four strains from each F-AFLP and rep-PCR cluster were selected for the DNA-DNA hybridisation. The results of DNA-DNA hybridisations of all examined strains are shown in Table 2.

DNA-DNA binding values obtained for four indole positive strains, BD 310 and PA 4 from onion and BD 435 and BD 442 from maize and *P. ananatis* LMG 2665<sup>T</sup>, varied between 90 and 100%. Since 70% DNA binding value was recommended as the minimum level of genotypic relatedness within a species (Wayne et al., 1987), these four isolates were identified as *P. ananatis*.

Strain BD 639 showed 89% DNA relatedness to BCC 105<sup>T</sup>. These two strains displayed an intermediate level of DNA similarity, 63 to 65%, to the type strain of *P. agglomerans*, and low levels to the known *Pantoea* species. Therefore, BD 639, and two indole negative strains, BD 500 and BD 502 (Goszczynska et al., 2007) that grouped with BCC 105<sup>T</sup> in the F-AFLP, rep-PCR and 16S rDNA dendograms, were identified as *P. vagens*.

DNA-DNA hybridisation data revealed that three strains from onion, BD 309, BD 377 and BD 390 displayed a high level of DNA relatedness, 90 to 100%, and low levels of relatedness to the known *Pantoea* species and *P. vagens*. The name *Pantoea allii* sp. nov. is proposed for this taxon.

### Phenotypic characteristics

**Utilisation of carbon sources.** On the UPGMA dendrogram of the Biolog data (Fig. 6), the strains used in the study formed four clusters. The biggest group consisted of 54 strains and included all strains identified as *P. ananatis* by molecular fingerprinting, *P. stewartii* subsp. *indologenes* and *P. allii* sp. nov. There was consistency in utilisation of 69 substrates on the GN2 plates among these strains, 41 positive and 28 negative reactions. No single test was able to differentiate between *P. ananatis* and *P. allii*. *P. stewartii* subsp. *indologenes*, however, could be distinguished from these two other species by its inability to utilise L-rhamnose, L-histidine and D,L, $\alpha$ -glycerol phosphate.

The *P. vagens* strains from maize and the *P. vagens* type strain BCC 105<sup>T</sup> clustered with *P. agglomerans*. The isolates within a cluster gave 41 positive and 27 negative reactions in Biolog GN2 plates. *P. vagens* differed from *P. agglomerans* by its ability to utilise nine substrates: D-melibiose, turanose, L-ornithine, D-serine, L-threonine and four acids, formic,  $\alpha$ -hydroxybutyric,  $\alpha$ -ketoglutaric and succinamic.

**API 20E.** The results of physiological and biochemical tests using the API 20E system separated 67 strains (Table 1) into six groups (Fig. 7). All *P. ananatis* and *P. allii* fell within a single cluster. These two species could not be distinguished from each other based on API 20E tests. Five *P. ananatis* strains isolated from onion seed did not produce acid from sucrose, unlike the other *P. ananatis* used in the study and 18 strains of *P. ananatis* studied by Mergaert et al. (1993).

Three strains of *P. vagans* formed a separate group in the dendrogram (Fig. 7). They gave positive reactions in the following tests:  $\beta$ -galactosidase, acetoin, gelatinase and produced acid from D-glucose, D-mannitol, inositol, L-rhamnose, D-sucrose, D-melibiose, and L-arabinose. They did not produce acid from D-sorbitol and amygdalin, indole from tryptophane, arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, citrate, H<sub>2</sub>S and urease. Although in another study (Goszczynska et al., 2007) three strains from maize differed from other *Pantoea* species by giving a positive reaction in tryptophane deaminase test, the type strain of *P. vagans*, BCC 105<sup>T</sup>, was negative for this test. In contrast to other indole negative *Pantoea* species, *P. vagans* did not produce acid from amygdalin, and could be distinguished by that characteristic.

**API 50CHE.** Thirty-three strains were examined by the analysis of anaerobic acid production from 48 substrates and the ability to hydrolyse esculin in the API 50CHE strips.

Contrary to Biolog and API 20E, *P. allii* could be differentiated from *P. ananatis* and other *Pantoea* species by the API 50CHE tests (Fig. 7). Five *P. allii* strains produced acid from at least one of the following compounds; D-adonitol, methyl- $\beta$ -D-xylopyranoside, L-sorbose, inulin and xylitol, while all other *Pantoea* isolates did not. Production of acid from D-adonitol, methyl- $\beta$ -D-xylopyranoside, L-sorbose and inulin, were not reported for members of the genus (Gavini et al., 1989; Mergaert et al., 1993).

Biochemical characteristics of *P. vagans* were additionally defined by the API 50CHE. The isolates produced acid from D-fucose, unlike other strains used in the study.

## DISCUSSION

Diseases caused by bacteria belonging to the genus *Pantoea* are emerging diseases in South Africa, and may have an increasing economic impact in the future. The causal agents, isolated from onion (Hattingh and Walters, 1981), *Eucalyptus* (Coutinho et al., 2002), onion seed (Gosczynska et al., 2006) and most recently from maize (Gosczynska et al., 2007), have been described as *P. agglomerans*, *P. ananatis* and *Pantoea* sp. closely related to *P. agglomerans*, respectively. The species allocation, with the exception *P. ananatis* from *Eucalyptus*, was based on a biochemical and physiological characterisation, analysis of the 16S rDNA sequences and, in the case of maize pathogens, F-AFLP genomic fingerprinting. Such a taxonomic system is insufficient for species delineation according to the recommendation of Wayne et al. (1987) and Stackebrandt et al. (2002). This study was performed to determine the accurate taxonomic position of bacteria from onion and maize in the genus *Pantoea*. To achieve this, a collection of strains from South African maize and strains pathogenic to onion isolated in South Africa and the USA were examined using a variety of methods, recommended for the taxonomic description of bacterial species (Stackebrandt et al., 2002).

Phenotypic characterisation confirmed that strains from maize and onion belong to the genus *Pantoea* and indicated, as expected, that at least two bacterial species were present. The 16S rDNA sequence analysis, however, revealed that three species could be present, as some strains from onion, thought to be *P. ananatis*, formed a separate cluster in the 16S rDNA tree (Fig. 5). However, 16S rDNA sequence analysis is known to be of limited value in terms of taxonomic resolution at the species level for members of *Enterobacteriaceae*, due to possible lateral transfers within the gene (Rayssiguier et al., 1989) and multiple copies of the 16S rRNA gene (Cillia et al., 1996).

Taxonomic relationships at the species level were assessed by rep-PCR and F-AFLP genomic fingerprints analysis and DNA-DNA hybridisation. All indole positive *Pantoea* from maize and the majority of strains from onion generated genomic fingerprints that were similar to that produced by the reference strains of *P. ananatis* (Fig. 3, Fig. 4). Four strains of that group, two from onion and two from maize, showed 90-100% DNA binding to *P. ananatis* type strain LMG 2665<sup>T</sup> (Table 2). As strains with similar genomic fingerprints are

genomically closely related (Gavini et al., 1989; Rademaker et al., 2000), all strains within *P. ananatis* rep-PCR and F-AFLP clusters are thus identified as *P. ananatis*.

The indole negative strains from maize, although similar to *P. agglomerans* by phenotypic tests and the 16S rDNA sequences, produced genomic fingerprints that clustered with *P. vagens* BCC 105<sup>T</sup> (Fig. 3, Fig. 4). BD 639 showed a high level, 89%, of DNA relatedness to BCC 105<sup>T</sup>. Although DNA bidding ratios of these two strains to *P. agglomerans* were between 63 and 65%, they should not be classified as a subspecies of *P. agglomerans*. The fingerprints of *P. vagens* were distinctly different from that of *P. agglomerans*, further supporting the establishment of a separate species to contain them.

The strains BD 390 and BD 309 were identified in a previous study as *P. ananatis* (Goszcynska et al., 2006). However, the genomic fingerprints generated by BD 309, BD 390 and three other isolates from onion, did not resemble that produced by *P. ananatis*, and formed a separate cluster in the F-AFLP and rep-PCR dendograms (Fig. 3, Fig. 4). The DNA-DNA hybridisation values among three strains of this cluster were between 90 and 100%, confirming that they belong to a single species. The most closely related type strain was *P. ananatis* with 44 to 57% DNA reassociation, below the 70% threshold allowed for species delineation (Wayne et al., 1987). The name *Pantoea allii* sp. nov. is proposed for this species.

Table 3 gives phenotypic characteristics useful in the differentiation of the species of the genus *Pantoea*. *P. vagens* could not be easily differentiated from *P. agglomerans* and *P. allii* from *P. ananatis* by an exclusive biochemical or physiological tests. A similar problem was reported by Gavini et al. (1989) with *P. agglomerans* versus *P. dispersa* and by Mergaert et al. (1993) concerning *P. ananatis* versus *P. stewartii* subsp. *indologenes*.

*Pantoea* strains should be classified and identified mainly based on genotypic characteristics, as identification based on phenotypic tests does not always lead to clear results (Gavini et al., 1989, Mergaert et al., 1993).

### Description of *Pantoea allii* sp. nov.

*Pantoea allii* [al'li.i. N.L. adj. *allii* from *Allium*, the genus of onion (*Allium cepa* L.)].

The description below is based on the data obtained for the five strains, BD 304, BD 309, BD 377, BD 380 and BD 390, isolated from onion plants with centre rot symptoms in the USA and from onion seed in South Africa. In pathogenicity tests, strains induce symptoms identical to those caused by *P. ananatis* on onion plants.

Gram-negative, non-capsulated, non-spore forming straight rods, motile. Colonies on nutrient agar and TGA are yellow, smooth, round, and convex with entire margins. They are facultatively anaerobic, oxidase negative and catalase positive. Cells tolerate up to 6% NaCl and grow at 30°C, 37°C and 40°C, but not at 4°C and 44°C.

*P. allii* does not produce arginine dihydrolase, lysine decarboxylase, ornithine decarboxylase, H<sub>2</sub>S, urease, tryptophane deaminase and gas from glucose. Citrate is utilised. Indole, acetoin, and β-galactosidase are produced.

*P. allii* strains produce acid from at least one of the following carbon sources: D-adonitol, methyl-β-D-xylopyranoside, L-sorbose, inulin and xylitol, while *P. ananatis* do not produce acid from this compounds. Other biochemical characteristics of *P. allii* at 30°C are shown in Table 3.

The following carbon sources are utilised at 30°C (as assessed by Biolog GN microplates), by 100% of strains: dextrin, tween 40, tween 80, N-acetyl-D-glucosamine, L-arabinose, D-arabitol, D-cellobiose, D-fructose, D-galactose, gentiobiose, α-D-glucose, inositol, α-D-lactose, lactulose, D-mannitol, D-mannose, D-melibiose, β-methyl-D-glucoside, D-raffinose, L-rhamnose, sucrose, D-trehalose, pyruvic acid methyl ester, succinic acid mono-methyl ester, acetic acid, cis-acconitic acid, citric acid, D-galacturonic acid, D-gluconic acid, D-glucosaminic acid, D-glucuronic acid, D,L-lactic acid, quinic acid, D-saccharic acid, succinic acid, bromosuccinic acid, D-alanine, L-alanine, L-alanyl-glutamic acid, L-histidine, L-proline, L-serine, urocanic acid, inosine, thymidine, glycerol, D,L,α-glycerol phosphate, α-D-glucose-1-phosphate and D-glucose-6-phosphate. The following carbon substrates are not utilised: α-cyclodextrin, N-acetyl-D-galactosamine, erythritol, L-fucose, turanose, xylitol, D-galactonic acid lactone, β-hydroxybutyric acid, p-hydroxyphenylacetic acid, itaconic acid, α-ketobutyric acid, α-ketoglutaric acid, α-ketovaleric acid, malonic acid, propionic acid, sebacic acid, L-alaninamide, hydroxy-L-proline, L-leucine, L-phenylalanine, L-pyroglutamic acid, L-threonine, D,L-carnitine, γ-aminobutyric acid, phenylethylamine, putrescine, 2-

aminoethanol and 2,3-butanediol. *P. allii* varies in the utilisation of the following carbon sources in the Biolog GN plates: glycogen, adonitol, maltose, D-psicose, D-sorbitol, formic acid,  $\alpha$ -hydroxybutyric acid,  $\gamma$ -hydroxybutyric acid, succinamic acid, glucuronamide, L-ornithine and D-serine.

The proposed type strain is BD 390, isolated from onion seed in South Africa.

## ACKNOWLEDGEMENTS

Thank the University of Ghent, Belgium, for doing DNA-DNA hybridisations.

Table 3. Differential characteristics of *Pantoea allii* and some biochemically similar species within the genus *Pantoea*.

Characteristic	1	2	3	4	5	6
<b>API 20E tests</b>						
Citrate utilisation	+	+	+	-	-	-
Tryptophane deaminase	-	-	-	d	-	-
Indole	+	+	+	-	-	-
Gelatinase	+	d	-	+	d	-
Acid from:						
Inositol	d	d	-	+	d	-
D-sorbitol	+	d	-	-	-	-
L-rhamnose	+	d	d	+	+	d
D-sucrose	+	d	+	+	+	+
Amygdalin	+	+	+	-	+	d
<b>API 50CHE tests</b>						
Esculin hydrolysis	+	d	d	d	+	-
Acid from:						
D-adonitol	d	-	-	-	-	-
Methyl- $\beta$ -D-xylopyranoside	d	-	-	-	-	-
L-sorbose	d	-	-	-	-	-
Inositol	+	+	+	+	d	+
D-sorbitol	+	d	-	-	-	-
Amygdalin	+	d	-	-	-	-
D-lactose	+	+	+	-	-	-
Inulin	d	-	-	-	-	-
Starch	-	-	-	d	-	-
Glycogen	-	-	-	d	-	-
Xylitol	+	-	-	-	-	-
D-fucose	-	-	-	+	-	-

+ , positive reaction for at least 90% of the strains; - , negative reaction for at least 90 % of the strains; d, 11-89% strains positive. 1, *Pantoea allii*; 2, *P. ananatis*; 3, *P. stewartii* subsp. *indologenes*; 4, *P. vagans*; 5, *P. agglomerans*; 6, *P. dispersa*

Data for *P. ananatis* and *P. stewartii* subsp. *indologenes* are from this study and Mergaert et al. (1993); for *P. agglomerans* and *P. dispersa* are from this study and Gavini et al. (1989).

Fig. 1. The symptoms induced by *Pantoea ananatis* (A) and *P. allii* (B) strains isolated from onion on onion leaves in pathogenicity tests. Two to four days after inoculation water soaked spots appeared on leaves that expanded into longitudinal, bleached-green lesions with chlorotic margins.

Fig. 1

Fig. 2. The symptoms produced by *P. ananatis* isolated from maize with brown stalk rot on maize SR 52. A, Four to six days after inoculation, small, 2-4 mm, light brown or dark green lesions developed around the inoculation point. Additionally, drops of yellow liquid slowly oozed from the lesion for two to three days. B, after 6 to 7 weeks, a single, long, vertical crack appeared on the injected internode. C, A dark brown, narrow lesion was present in an internal stem tissue along the crack. D, Browning of the internal tissue in an upper internode. The symptoms induced by *P. vagans* were indistinguishable from those induced by *P. ananatis*.

Fig. 2

Fig. 2

Fig. 3. A dendrogram showing the relationships between *Pantoea* strains used in the study based on F-AFLP fingerprints. *P. allii* strains are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics.

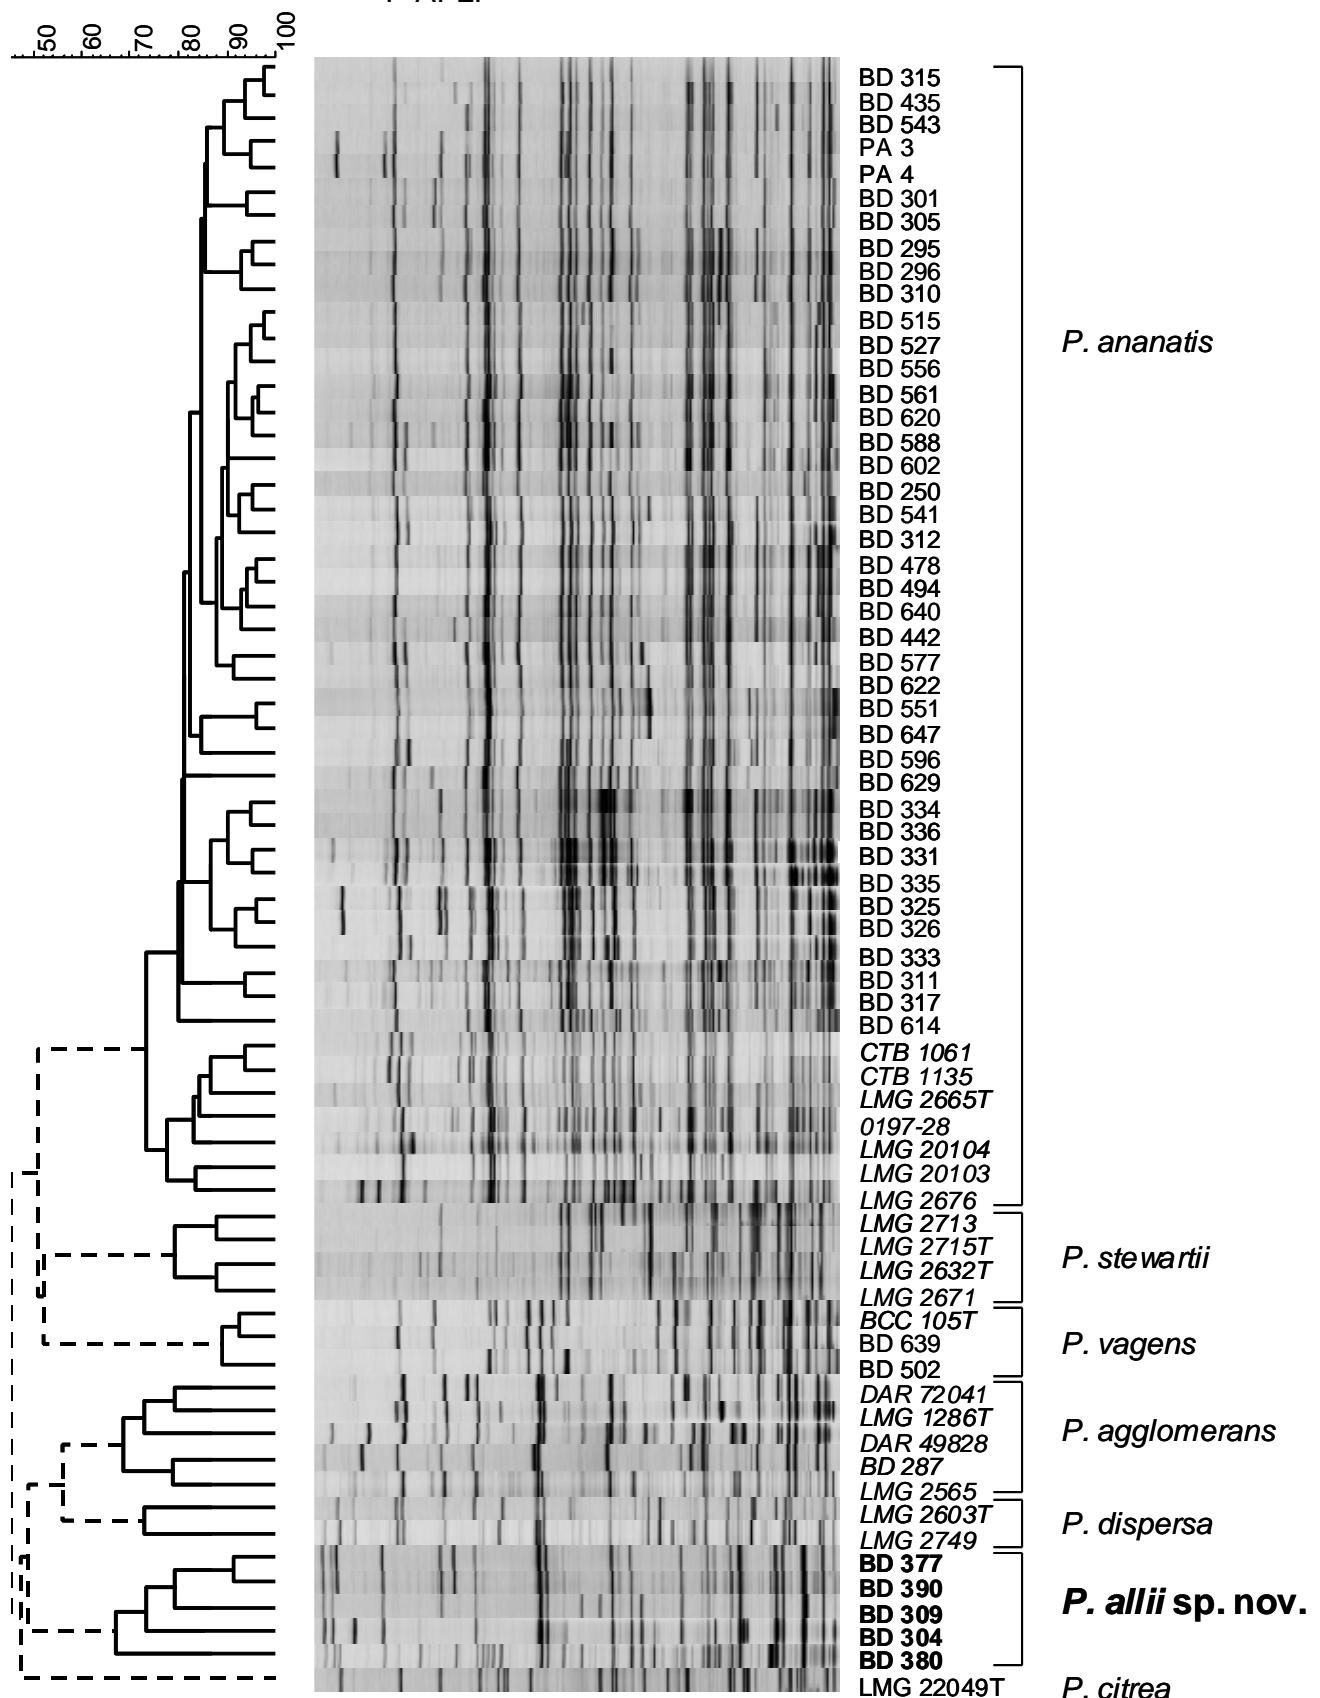

Fig. 4. A dendrogram showing the relationships between the *Pantoea* strains used in the study based on the rep-PCR fingerprints. *P. allii* are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics.

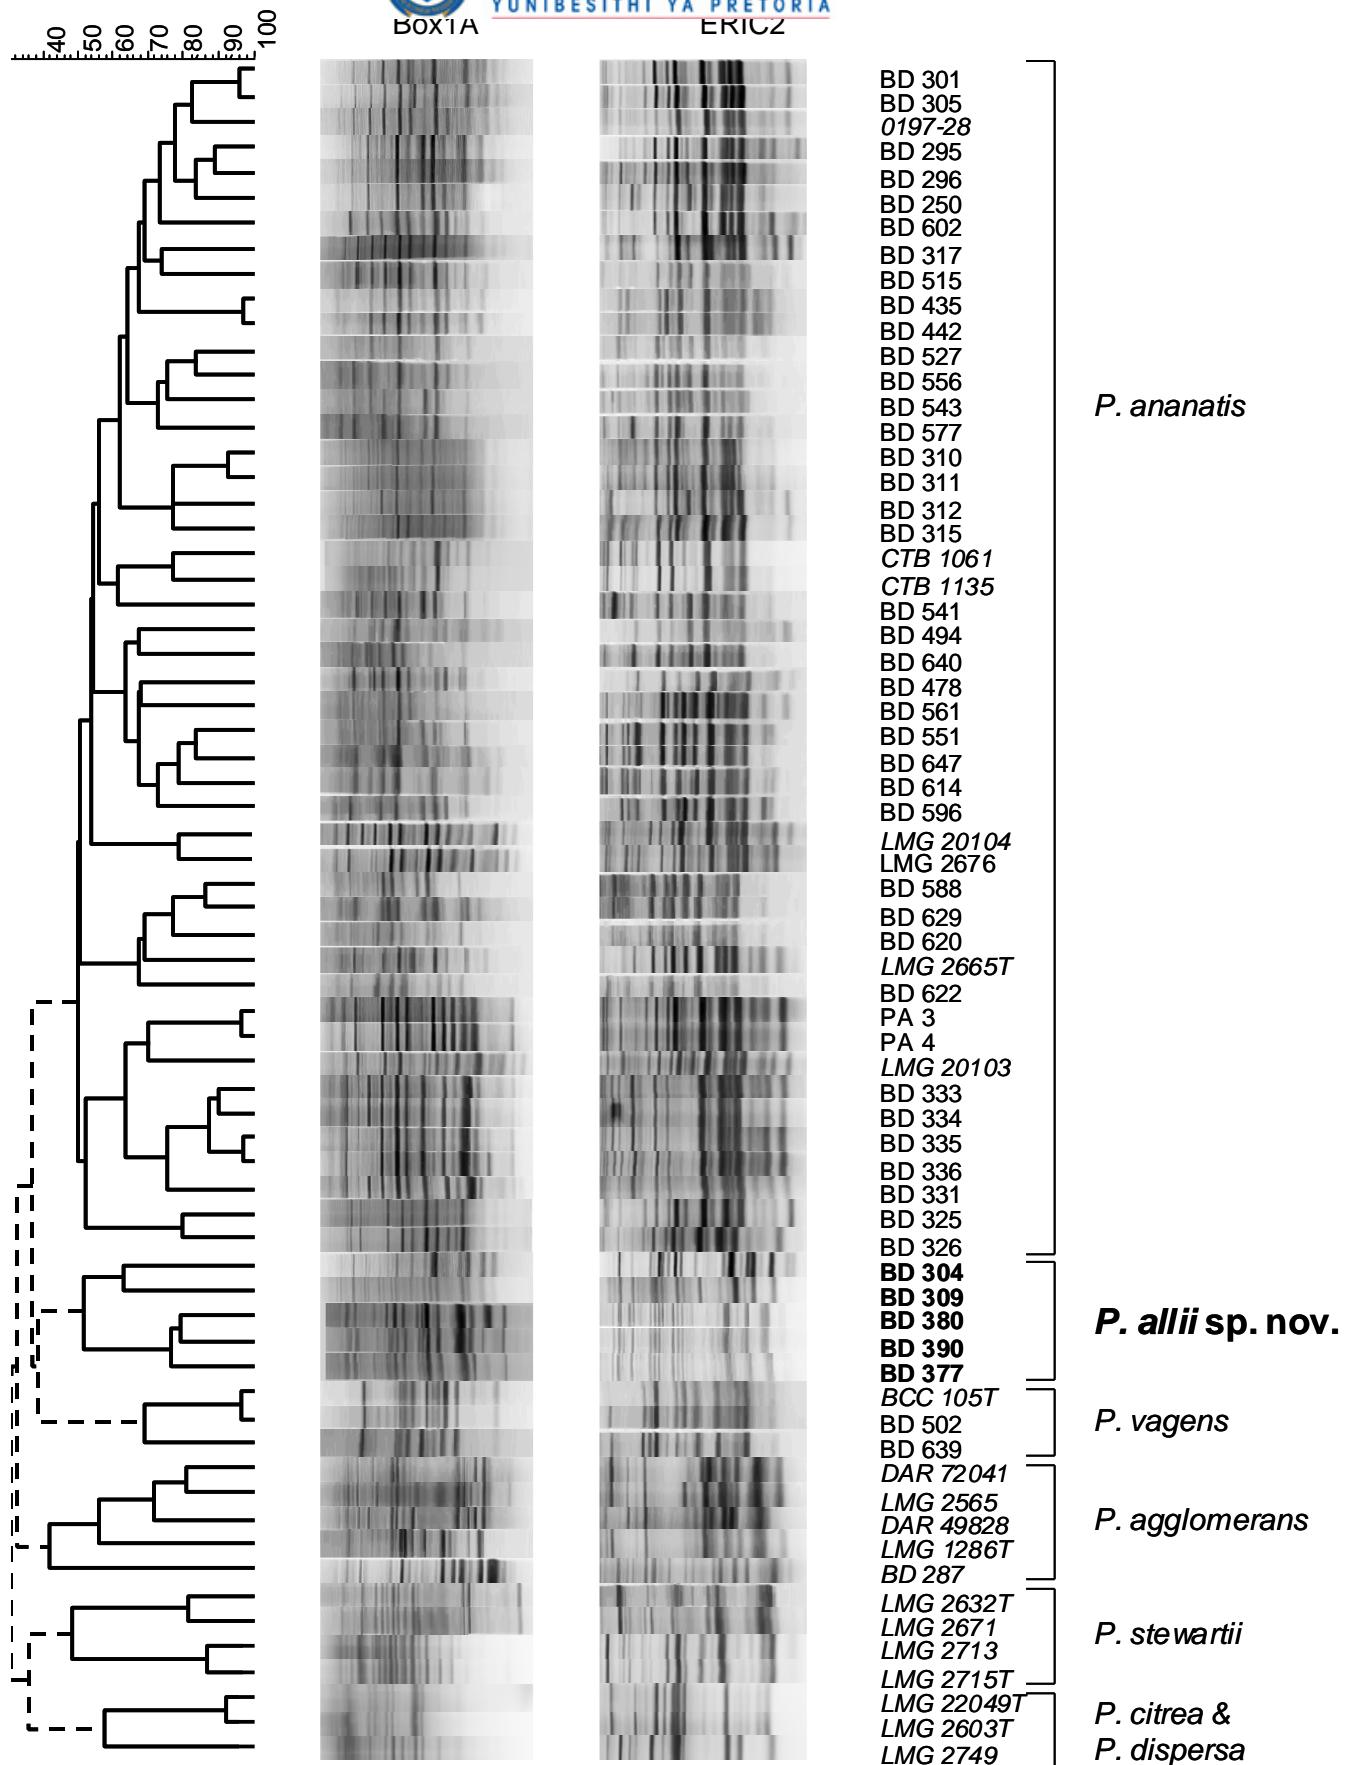

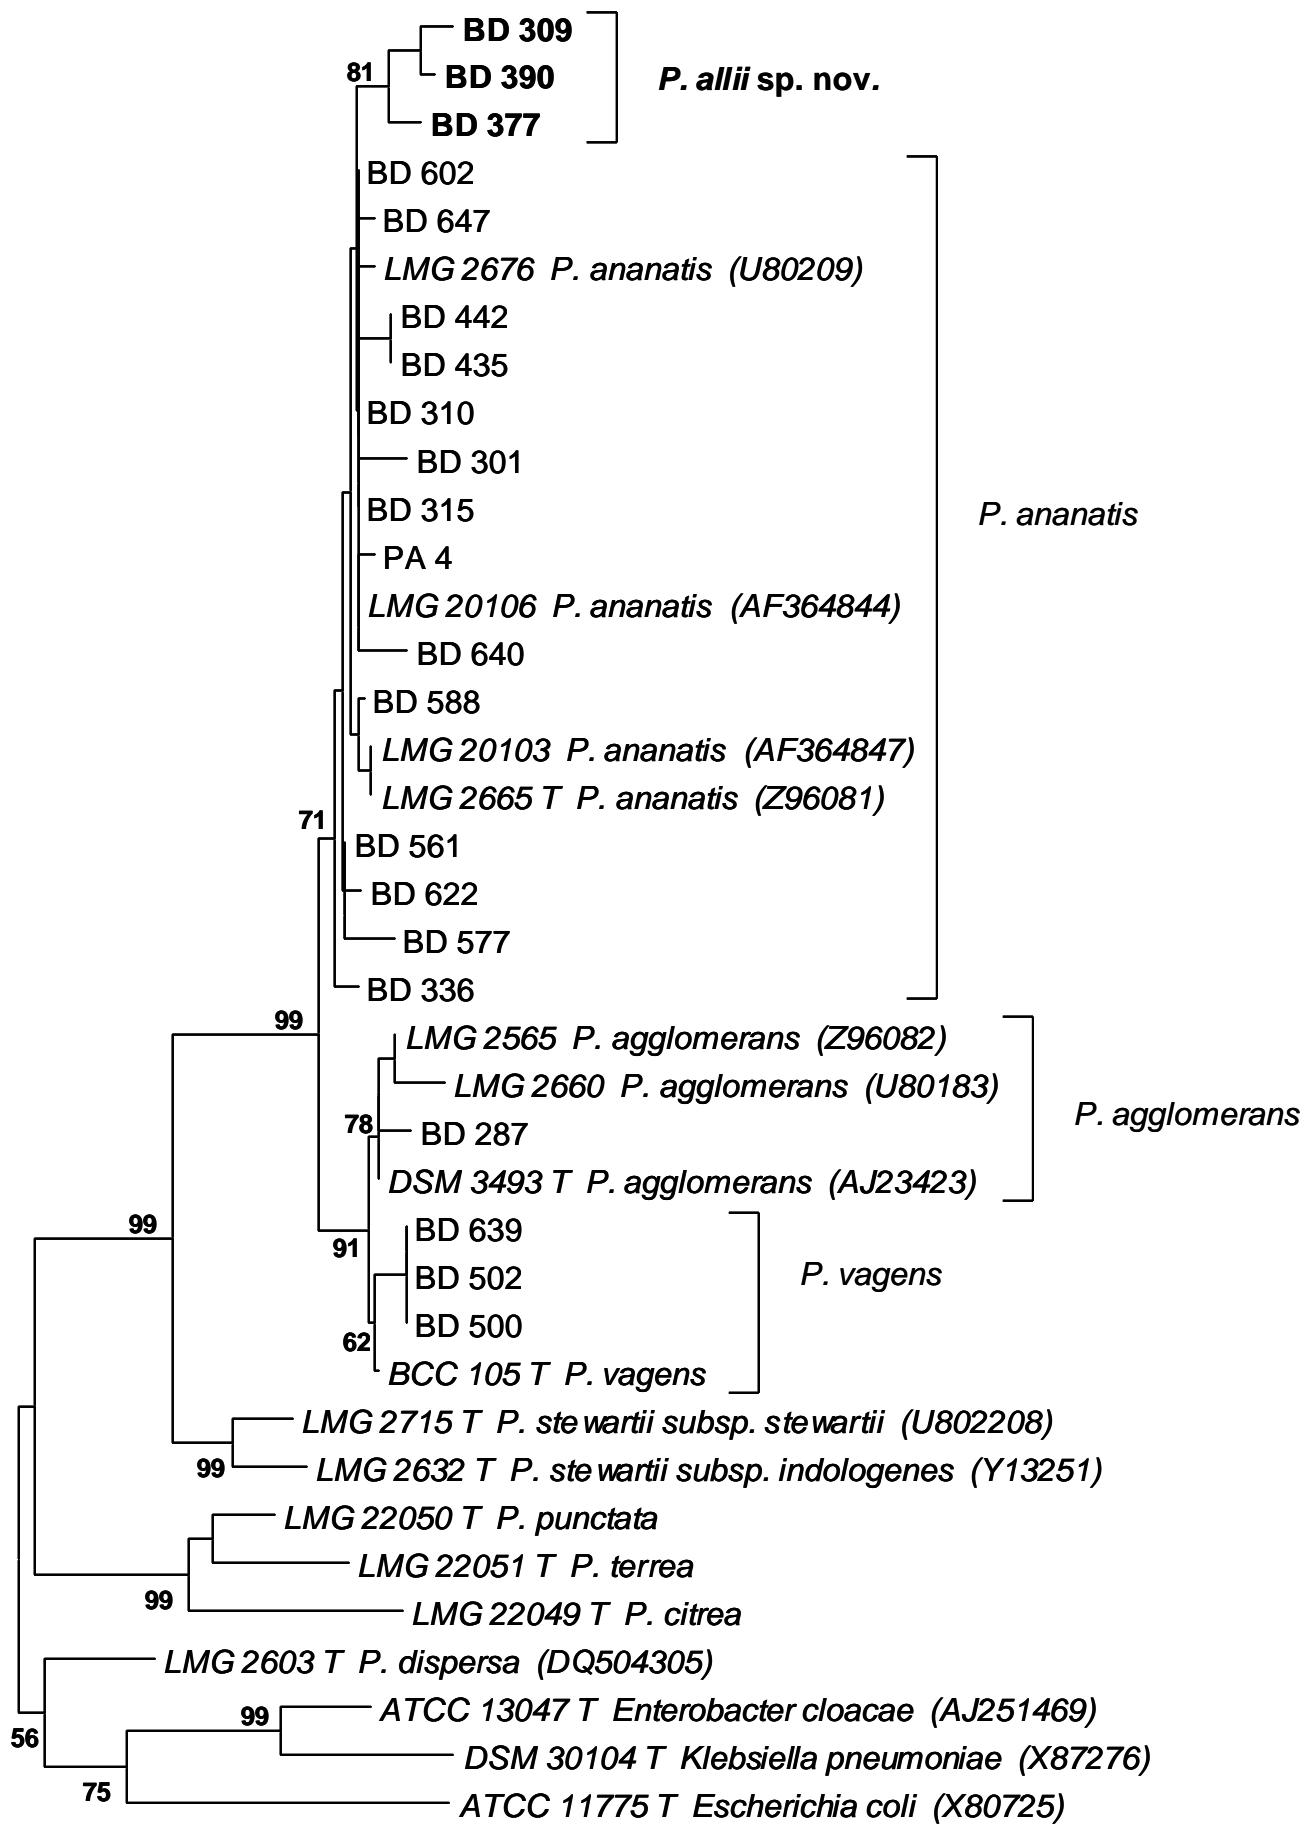

Fig. 5. Neighbour-joining tree reflecting the phylogenetic position of *Pantoea* strains from maize and onion based on 16S rDNA sequences. Numbers at branching points indicate bootstrap values derived from 1000 samples. The bar represents genetic distance. *P. allii* strains are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics.

The 16S rDNA accession numbers of maize and onion strains:

Maize: BD 602, DQ195522; BD 647, DQ195525; BD 435, AY89864; BD 442, AY898643; BD 640, DQ195524; BD 588, DQ133548; BD 561, DQ133546; BD 622, DQ195523; BD 577, DQ133547; BD 639, DQ512489; BD 500, DQ849042; BD 502, DQ849043. Onion: BD 309, AY579210; BD 390, AY530795; BD 377, DQ512491; BD 310, AY579211; BD 301, AY579209; BD 315, AY579212; PA 4, AY530796; BD 336, AY530794; BD 287, AY530797.

0.005

Fig. 6. Relationships among 67 *Pantoea* strains, including strains isolated from onion and maize, based on Biolog GN microplate substrate utilisation patterns. *P. allii* strains are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics.

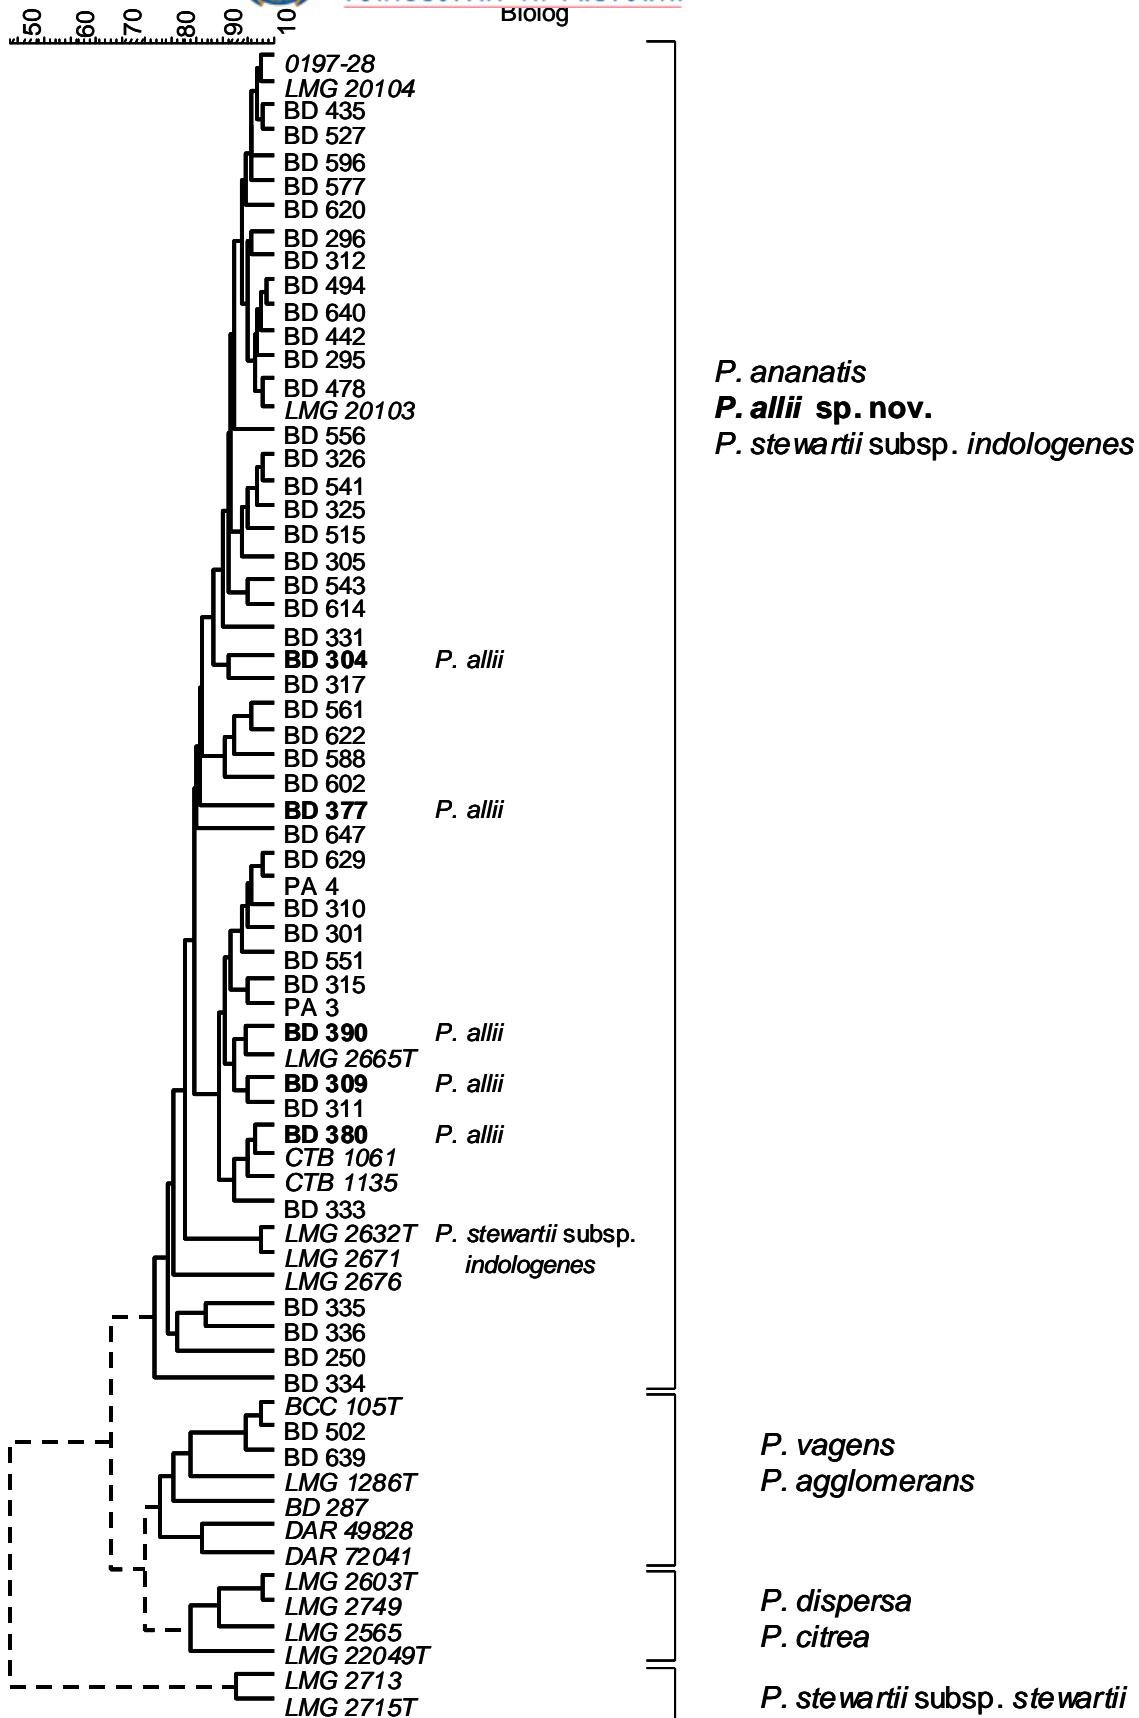

Fig. 7. Relationships among 67 *Pantoea* strains, including strains isolated from onion and maize, based on API 20E tests. *P. allii* strains are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics. A black rectangle indicates a positive reaction in the test while a white rectangle indicates a negative reaction in the test.

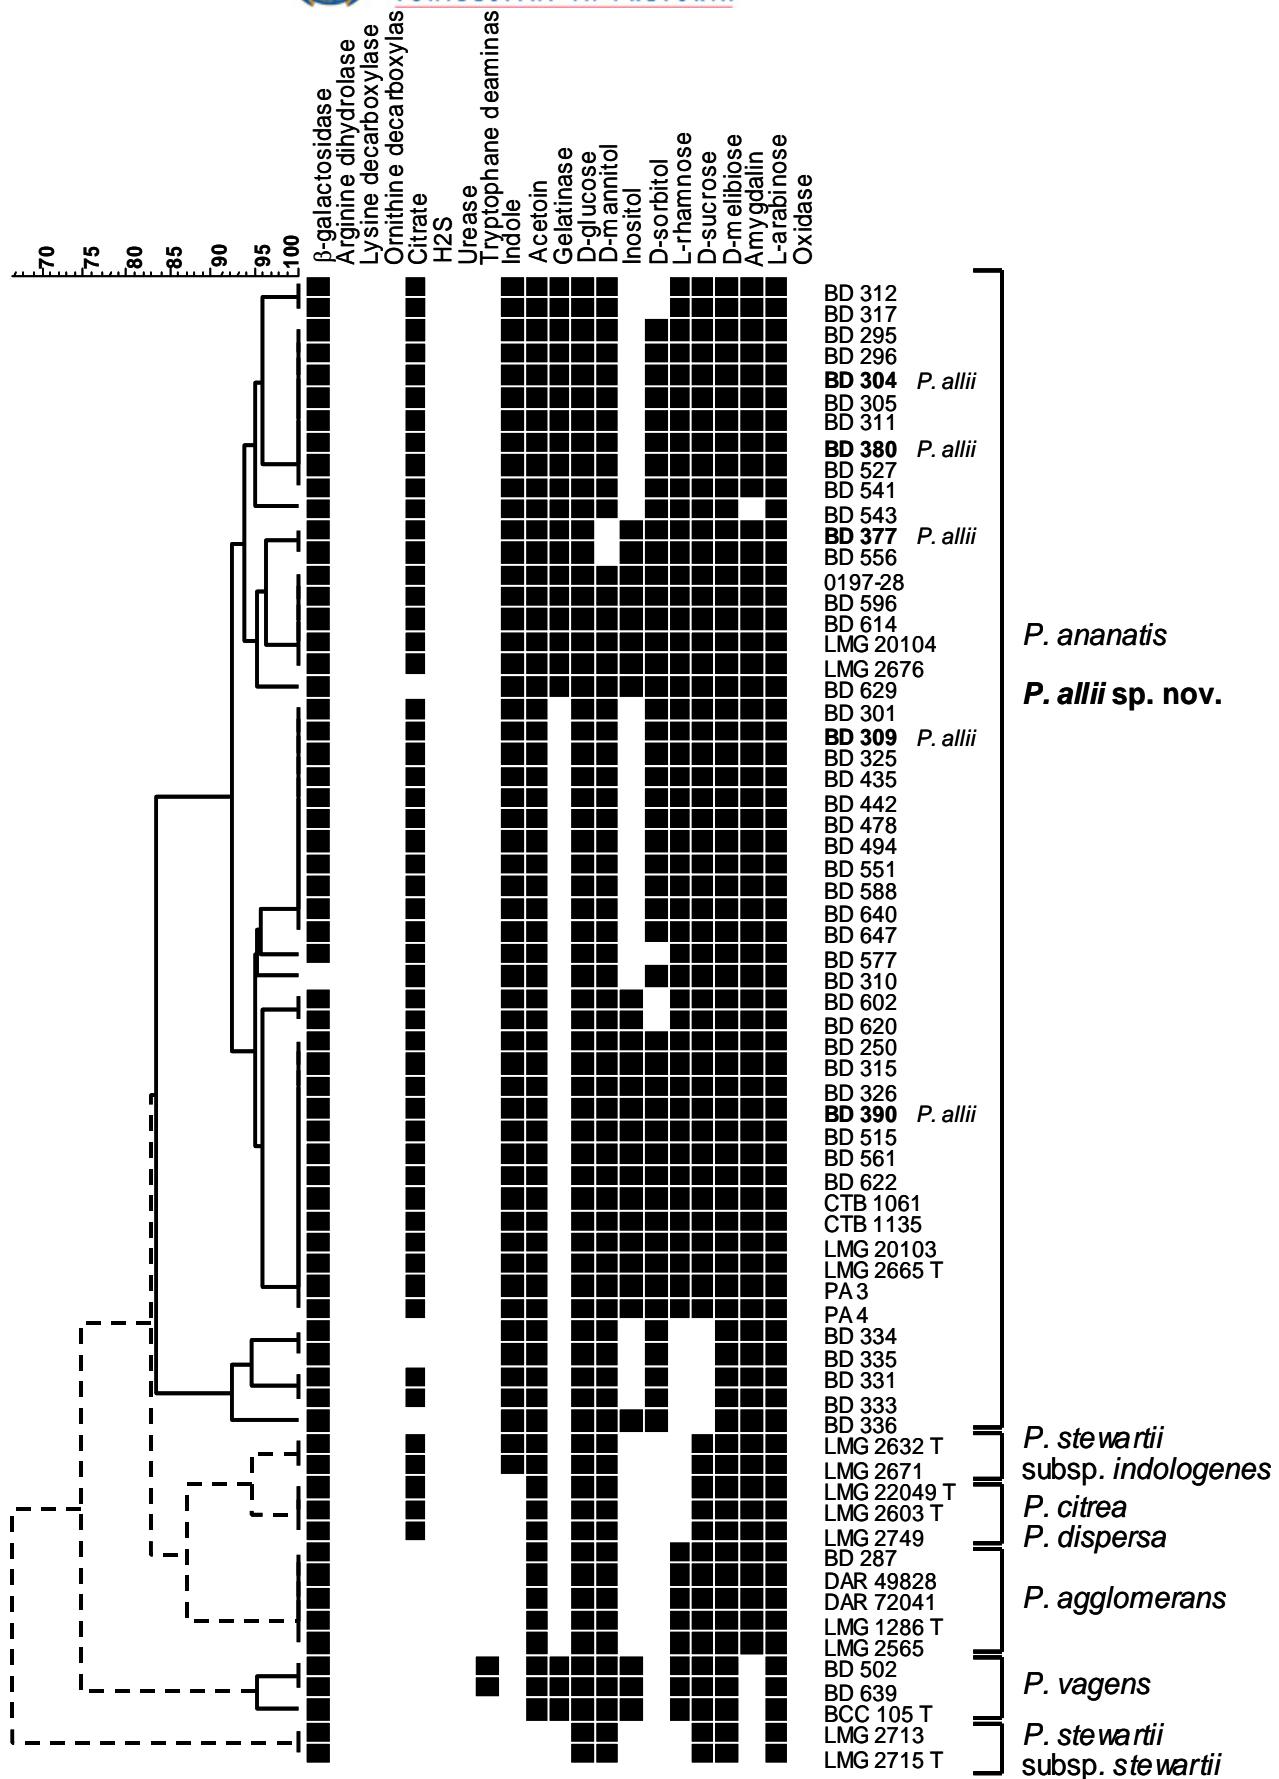

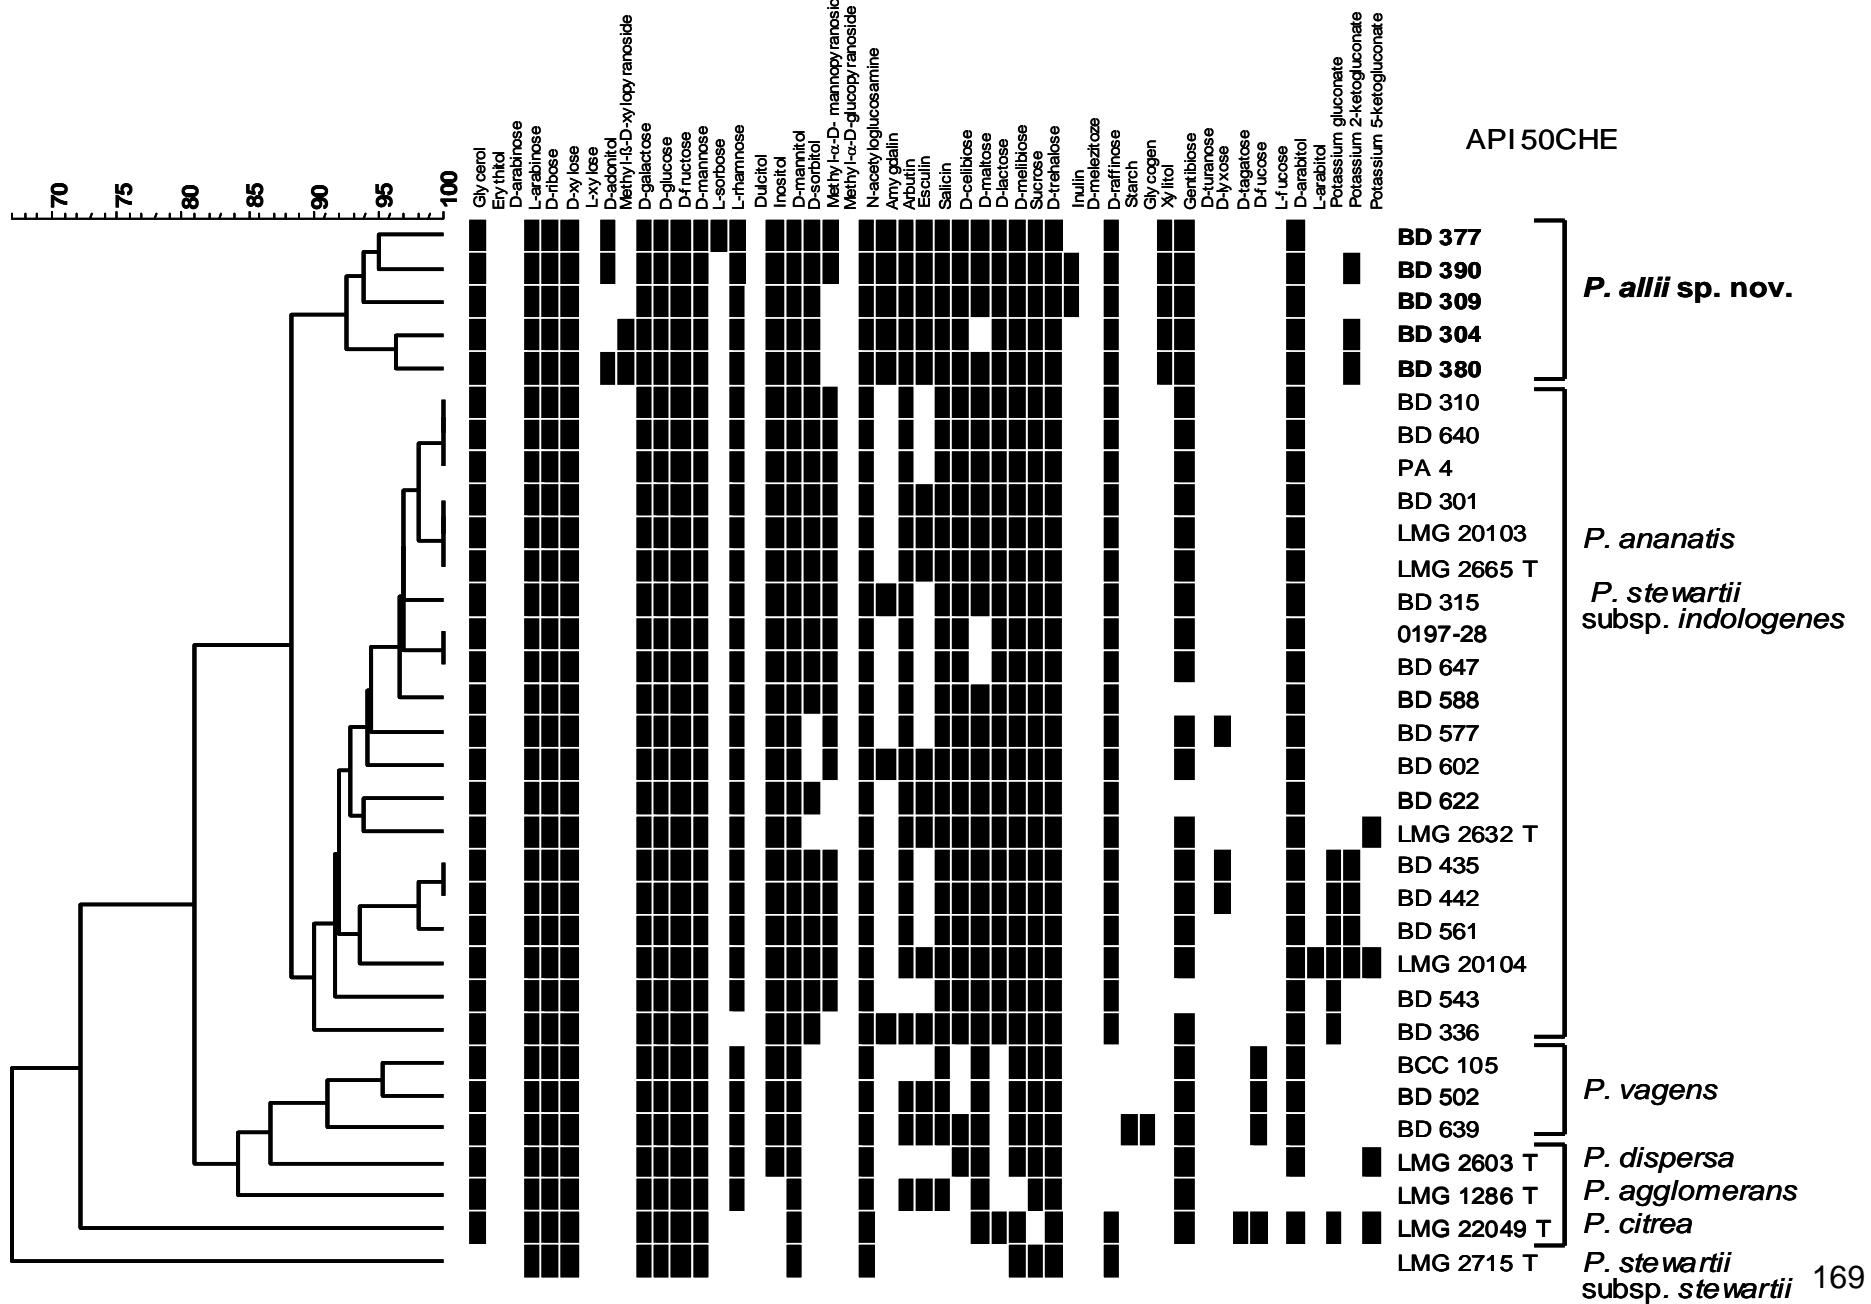

Fig. 8. Relationships among 33 selected *Pantoea* strains, based on API 50CHE tests. *P. allii* strains are highlighted in bold. Reference strains, including the type strains of *Pantoea* species, are in italics. A black rectangle indicates a positive reaction in the test while a white rectangle indicates a negative reaction in the test.

**APPENDIX A:** Multiple Sequence Alignment, 16S rDNA sequences of *P. allii*, *P. ananatis*, *P. agglomerans*, *P. vagens*, *P. stewartii* subsp. *stewartii*, *P. stewartii* subsp. *indologenes*, *P. punctata*, *P. terrea*, *P. citrea*, *P. dispersa*, *Enterobacter cloacae*, *Klebsiella pneumoniae* and *Escherichia coli*. Number of sequences: 38

Maximum length: 1560

Strains:

*P. allii*: BD 309, BD 390, BD 377

*P. ananatis*: BD 301, BD 315, LMG 20106, BD 442, BD 435, BD 310, LMG 2676, BD 647, PA 4, BD 602, BD 640, BD 588, LMG 20103, LMG 2665T, BD 561, BD 622, BD 577, BD 336

*P. agglomerans*: LMG 2565, LMG 2660, BB 287, DSM 3493 T (=LMG 1286 T)

*P. vagens*: BCC 105 T, BD 500, BD 502, BD 639

*P. stewartii* subsp. *stewartii*: LMG 2715 T; *P. stewartii* subsp. *indologenes*: LMG 2632 T;

*P. punctata*: LMG 22050 T; *P. terrea*: LMG 22051 T; *P. citrea*: LMG 22049 T; *P. dispersa* LMG 2603 T

*Enterobacter cloacae*: ATCC 13047 T; *Klebsiella pneumoniae*: DSM 30104 T; *Escherichia coli* ATCC 11775 T

The differences in nucleotides between *P. allii* and *P. ananatis* are marked in green: BD 309 nucleotide numbering, position 378-179.

The differences in nucleotides between *P. vagens* and *P. agglomerans* are marked in blue: BCC 105 nucleotide numbering, position 375-376.

Upper line in the alignment:

symbol “ - ” indicates sites excluded from the construction of phylogenetic tree (Fig. 3).

Symbol “ \* ” indicates sites included in the construction of phylogenetic tree (Fig. 3).
