DEPARTMENT: MATERIALS SCIENCE AND METALLURGICAL ENGINEERING

DEGREE: PHILOSOPHIAE DOCTOR
(METALLURGICAL ENGINEERING)

ABSTRACT

The aim of this study was to arrive at a fundamental understanding of kimberlite weathering and of factors which affect the rate and extent of weathering. Weathering was evaluated by measuring the change in size distribution after immersing crushed kimberlite in solutions of various compositions. Reproducibility of the measurements was found to be good, with the cumulative mass passing a given size differing by 7% or less, as tested for various weathering conditions.

Kimberlite mineralogy, specifically the swelling clay content, was found to play a central role: kimberlite ores containing no swelling clay were not prone to weathering under any of the conditions tested.

The cation exchange capacity (CEC) correlates well with the swelling clay content and with the weathering behaviour. The cation exchange capacity may be used in conjunction with the swelling clay content, as a predictor of possible kimberlite behaviour; however, given the relative complexity and cost of measuring swelling clay content (by X-ray diffraction), the CEC is the preferred parameter for practical use.

Cations in the weathering solution have a strong effect on kimberlite weathering; the strength of the effect followed the series Cu$^{2+} >$ Li$^+ >$ Fe$^{2+} >$ Ca$^{2+} >$ Fe$^{3+} >$ Mg$^{2+}$, whereas K$^+$ and NH$_4^+$ stabilised the kimberlite somewhat against weathering. This sequence was in reasonable
correlation with the ionic potential (ratio of valency to ionic radius), but with exceptionally strong weathering effects of Cu$^{2+}$, and (to a lesser extent) of Li$^+$ and Fe$^{2+}$. The strong effect of the latter group of cations may be related to their tendency to adsorb onto other crystal sites in addition to the interlayer – the associated change in surface energy can change the fracture behaviour of the kimberlite.

Measurement of the layer spacing of the swelling clay (by X-ray diffraction) showed no correlation between the weathering effect of a cation and the associated thickness of the interlayer. For solutions of cupric ions, the identity of the anion (chloride or sulphate) has little effect on weathering. The size of the crushed kimberlite ore similarly has little effect on the relative extent of size degradation by weathering.

The concentration of cupric ions affects weathering, as does the weathering time – although 85% of the weathering caused by 30 days' exposure was found to occur within the first 24 hours. Increasing the temperature to 40°C (in a magnesium chloride solution) also increased weathering strongly. The kinetics of exchange of cuprous and potassium ions was measured (for two different kimberlites); the apparent reaction order (with respect to the concentration of exchanging cations in solution) varied between 1 and 3.5, and exchange of potassium was more rapid.

This work has practical implications for in-plant processing of kimberlite, possible alternative kimberlite processing routes which eliminate one or more crushing steps, and for the stability of mine tunnels which pass through kimberlite.

KEYWORDS: Kimberlite, weathering, swelling, mineralogy, clay minerals, accelerated weathering, cation exchange
ACKNOWLEDGEMENT

Firstly I thank the Lord Jesus Christ for the abilities and talents He blessed me with. Also for His divine inspiration and for giving me hope in the times it felt that there was none. I thank my husband for his continued support and understanding and for always being there. I thank Dr. Thys Vermaak for his technical support and also friendship during this time. I would also like to thank the University of Pretoria colleagues, especially Sarah Havenga for her administrative functions and her friendship. I am grateful to my parents for the opportunities they provided, for always being there and supporting me. I am grateful to De Beers, especially Mr. Pete Sergeant for his contributions and Richard Kekana for the supply of ore resources. Other De Beers colleagues that contributed are Leon Kruger and Serkan Saydam. Thanks to Fanie Kruger at Mintek for the hours spent on XRD work to characterise the mineralogy and also Sabine Verryn at the University of Pretoria. Prof Pistorius deserves a special acknowledgement for his time, technical guidance, editing and contributing to my personal growth.

My wish is that this study will really improve the understanding of weathering and the impact thereof on kimberlite material. I hope wholeheartedly that this goal was achieved.

Heb 13:21 May God make you perfect in every good work to do his will, working in you that which is well pleasing in his sight, through Jesus Christ; to whom be glory forever and ever.

Figure 62. Visual appearance of Dutoitspan ore (initial size -26.5 + 22.4 mm) weathered in a 0.1 M cupric sulphate medium for 6 days.

Figure 63. Visual appearance of Dutoitspan ore (initial size -26.5 + 22.4 mm) weathered in a 0.4 M cupric sulphate medium for 6 days.

Figure 64. Results of the investigation to determine the influence of cation concentration. The tests were conducted on 1.5 kg of -26.5 +22.4 mm Dutoitspan ore. Copper sulphate concentrations were 0.005, 0.025, 0.05, 0.1, 0.2 and 0.4 M. The weathering time was constant at 6 days.

Figure 65. Weathering as a function of cation (cupric) concentration. The weathering is reported as the cumulative percent passing 14.2 mm from figure 64.

Figure 66. Results of the investigation of the influence of temperature on the weathering behaviour. The results include the standard test at room temperature and the standard test at 40 °C. The weathering tests in a 0.2 M MgCl₂ solution for 6 days at room temperature and 40 °C are also shown. All the tests were done on a 1.5 kg (initial size – 19 + 16 mm) Dutoitspan kimberlite sample.

Figure 67. Results of tests to determine the influence of the type of anion on weathering. Tests conducted on a 1.5 kg -26.5 + 22.4 mm Dutoitspan ore sample at 0.3 M cupric chloride and cupric sulphate solution for 6 days.

Figure 68. Results of the investigation to determine the influence of particle size. The tests were conducted in 0.2 M magnesium chloride solution for 6 days. The particle sizes used were -26.5 + 22.4, -22.4 + 19, -19 + 16 and -16 + 13.2 mm, using Dutoitspan ore.

Figure 69. Results from the investigation of particle size. Comparison of the size distribution curves for the unweathered and weathered states at 70 % of the starting material size.

Figure 70. Investigation of the influence of milling on weathering tests. Weathering tests were performed in a 0.2 M cupric sulphate solution (initial size - 26.5 + 22.4 mm) Dutoitspan ore for 12 hours and the unmilled and milled sample product size distributions compared.

Figure 71. Investigation of the influence of potassium on weathering tests. Weathering tests were performed on a 250 - 300 g -16 + 13.2 mm Dutoitspan kimberlite in a 0.5 M potassium solution for 8, 48 and 144 hours.

Figure 72. Investigation of the influence of copper on weathering tests. Weathering tests were performed on a 250 - 300 g -16 + 13.2 mm Dutoitspan kimberlite in a 0.5 M copper solution for up to 15 days.

Figure 73. Comparison of the effect of copper (swelling cation) on the left and potassium (stabilising cation) on the right and their effect on the weathering of kimberlite (photos taken after 6 days for potassium and 15 days for copper medium).

Figure 74. Venetia K1 Hypabyssal North East kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.
Figure 75. Venetia K1 Hypabyssal South kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 76. Venetia K1 TKB East kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 77. Venetia K2 South kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 78. Venetia K2 North East kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 79. Venetia K2 West kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 80. Venetia K8 unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 81. Venetia Red kimberlite unweathered (left) compared to the weathered product (right). Weathering was done in a 0.05 M cupric sulphate solution for 6 days.

Figure 82. Results of weathering tests performed on Venetia kimberlites (-26.5 + 22.4 mm) in a 0.05 M cupric sulphate solution for 6 days.

Figure 83a. Comparing weathering results with the smectite content of Venetia ores. Weathering is shown as log cumulative % passing at 10.3 mm from figure 82 (6 days’ weathering in 0.05 M copper sulphate).

Figure 83b. Comparing weathering results with cation exchange capacity of Venetia ores. Weathering is shown as log cumulative % passing at 10.3 mm from figure 82 (6 days’ weathering in 0.05 M copper sulphate).

Figure 84. Repeatability of the weathering tests were evaluated by triplicate tests at 0.025, 0.1 and 0.5 M copper concentration. Tests were done on 300 g, -16 + 13.2 mm Dutoitspan kimberlite.

Figure 85. ICP analysis results displaying the steady decrease of the concentration of copper in the weathering solution as a function of time. The lines are fitted curves for simple nth - order kinetics (parameters of curve fits in table 25).

Figure 86. ICP analysis results displaying the release of sodium, potassium, calcium and the sum of minor cations (K⁺, Ca²⁺, Mg²⁺ and Al³⁺) from the kimberlite into the 0.025 M copper solution.

Figure 87. ICP analysis results displaying the release of sodium, potassium, calcium and the sum of minor cations (K⁺, Ca²⁺, Mg²⁺ and Al³⁺) from the kimberlite into the 0.1 M copper solution.

Figure 88. ICP analysis results displaying the release of sodium, potassium, calcium and the sum of minor cations (K⁺, Ca²⁺, Mg²⁺ and Al³⁺) from the kimberlite into the 0.5 M copper solution.

Figure 89. ICP analysis results displaying the release of sodium from the kimberlite into the solution at 0.025, 0.1 and 0.5 M copper concentration.

Figure 90. ICP analysis results displaying the release of the sum of other cations (K⁺, Ca²⁺, Mg²⁺ and Al³⁺) from the kimberlite into the solution at 0.025, 0.1 and 0.5 M copper concentration.

Figure 91. A plot of log dC/dt vs. log (C-C∞) for the 0.025 M copper weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 92. A plot of log dC/dt vs. log (C-C∞) for the 0.1 M copper weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 93. A plot of log dC/dt vs. log (C-C∞) for the 0.5 M copper weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 94. ICP analysis results displaying the steady decrease of the concentration of potassium in the weathering solution as functions of time. The lines are fitted curves for simple n th - order kinetics (parameters in table 30).
Figure 95. ICP analysis results displaying the increase in the concentration of sodium in the potassium weathering solution as functions of time.
Figure 96. ICP analysis results displaying the increase in the concentration of the sum of calcium and magnesium in the potassium weathering solution as functions of time.
Figure 97. A plot of log dC/dt vs. log (C-C∞) for the 0.1 M potassium weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 98. A plot of log dC/dt vs. log (C-C∞) for the 0.5 M potassium weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 99. A plot of log dC/dt vs. log (C-C∞) for the 1 M potassium weathering test. Time in hours, (C-C∞) in mmol/l and dC/dt in mmol/(lxh).
Figure 100. A plot of t0.5 (time to reduce the difference between the exchanging cation concentration and the equilibrium concentration to half of the original difference) vs. log C∞-C for the copper and potassium data.
Figure 101. Langmuir adsorption isotherm for kimberlite treated with copper at 0.025, 0.1 and 0.5 M and treated with potassium at 0.1, 0.5 and 1 M.
Figure 102. Cation exchange constants as published by Bruggenwert and Kamphorst (1982) as a function of ionic potential.
Figure 103. Experimentally determined cation exchange constants as a function of ionic potential.
Figure 104. XRD scans (5.5 – 8 ° 2θ) of Dutoitspan kimberlite after exposure to copper solutions for 4 hours, 8 hours, 2 days, 7 days and 30 days.
Figure 105. XRD scans (5.5 – 8 ° 2θ) of Venetia Red kimberlite after exposure to a 1.5 M potassium chloride solution for 4 hours.
Figure 106. Visual results of the agglomeration test showing the degree of agglomerated ore on the metal piece.
Figure 107. Comparing weathering results with the agglomeration test of Venetia ores. Weathering is shown as log cumulative % passing at 10.3 mm from figure 82 (6 days’ weathering in 0.05 M copper sulphate).
Figure 108. Agglomeration test results for kimberlites dried at 100 °C and then wetted in distilled water for 2 hours.

ABBREVIATIONS

XRD: X-Ray Diffraction
XRF: X-Ray Fluorescence
Cph: Carats per hundred tons of ore
ESP: Exchangable Sodium Percentage
CEC: Cation Exchange Capacity
REE: Rare Earth Elements
TKB: Tuffisitic Kimberlite Breccia
HYP: Hypabyssal Kimberlite
ppm: Parts per million
s: Seconds
µm: micrometer

LIST OF APPENDIXES

Appendix A: Specifications on XRD work done at University of Pretoria and Mintek
Appendix B: Original XRD Data
Appendix C: Size distribution data
Appendix D: Slake Durability data
