Song Structure
and
Syllable Repertoires
in the European Sedge Warbler,
_Acrocephalus schoenobaenus_
by
Neil Samuel Hugh Wilson

Thesis submitted in fulfilment of the requirements for the degree of
Master of Science
Department of Zoology and Entomology
Faculty of Natural, Agricultural and Information Sciences
University of Pretoria

Advisor: Professor J. W. H. Ferguson

February 2001
I dedicate this thesis to the individuals who have enriched my life in many non-material ways:
The Sedge Warblers of Wraysbury Lakes
My adviser, Professor Willem Ferguson
Professor Hugh Paterson
My late father, Leon
My mother, Marion; brother, Peter and sister, Cheryl
My sons, Simon and Ben
My partner, Annie
My late aunt, Ethel Gordon and late uncle, Boris Wilson.
“...And sedge-warblers, clinging so light
To willow twigs, sang longer than the lark,
Quick, shrill, or grating, a song to match the heat
Of the strong sun, nor less the water's cool,
Gushing through narrows, swirling in the pool.
Their song that lacks all words, all melody,
All sweetness almost, was dearer then to me
Than sweetest voice that sings in tune sweet words.
This was the best of May – the small brown birds
Wisely reiterating endlessly
What no man learnt yet, in or out of school.”

From the poem, Sedge-Warblers by Edward Thomas
(Born London, 1878)
“science never imposes anything, science states. Science aims at nothing but making true and adequate statements about its object. The scientist only imposes two things, namely truth and sincerity, imposes them upon himself and upon other scientists.”

Summary

My thesis defines the temporal, acoustic frequency and sequential structure of Sedge Warbler song qualitatively and quantitatively in a rigorous way using a range of uni- and multivariate techniques. The implications of this definition are considered in terms of previous studies involving Sedge Warbler song structure, and the communication system of this species. Sedge Warbler song is extremely complex and variable and has provided fertile ground for the study of sexual selection by female choice. This complexity and variability present a formidable challenge for quantitative definition, which has not been achieved in a rigorous way in this species before. Despite this, structural features such as syllables, syllable types and songs have been used quantitatively to derive measures such as estimated syllable repertoire size and to test hypotheses about evolutionary function. Syllable types that comprise the repertoires of males have not been defined at all, yet are considered to play a central role in sexual selection as an honest indicator of male quality to prospecting females.

Quantitative evidence is presented to show that syllables and their component elements are the basic vocal units in Sedge Warbler communication and that songs are artificial units. This evidence has implications for the interpretation of Sedge Warbler communication and for studies that depend on a song as a discrete vocal unit. Element and inter-element durations are found to be within the limits of auditory discrimination in songbirds. The considerable variability in the cyclical behaviour of syllable, syllable type and mean inter-syllable duration rates, and out of phase variation between them in each male, indicate higher levels of variability and complexity in the structure of Sedge Warbler song than originally described. This variability and complexity may promote attention levels in prospecting conspecifics and may reduce specific neuromuscular activity and fatigue that will be important in sustaining the almost continuous singing over long periods, characteristic of male Sedge Warblers. The out of phase variation between syllable and syllable type rate cycles together with significant differences between song samples of different males in both these variables may provide a basis for them to function as independent multiple cues in female choice. Analysis of the relationships between inter-syllable duration, syllable rate and syllable type rate indicate that there are constraints on the possible sexually selected traits of syllable and syllable type rates. Significant differences between song samples of different males in element, inter-element, syllable and inter-syllable durations and syllable rate
may provide a basis for individual recognition, if differences shown reflect differences between males.

The size and composition of the complete estimated syllable repertoires of two male Sedge Warblers are determined by quantitative and qualitative analyses which yield very similar results, but appreciably higher estimates of size than previous qualitative studies. This discrepancy may be due to subjectivity of syllable type determination and insufficient song sample duration of the previous studies, which are likely to have produced inaccurate estimates of syllable repertoire size. This error may affect the significant relationships found between repertoire size and other variables in previous studies. Significant temporal and acoustic frequency differences found between syllable types are well within songbird auditory system resolving power, and form a basis for syllable types to function as fundamental units of syllable variation and for categorical perception of syllable types in the Sedge Warbler.

Quantitative and qualitative evidence is presented for structural distinctness of syllable types in a population of Sedge Warblers within and between breeding seasons. This evidence is consistent with syllable types functioning as fundamental units of Sedge Warbler vocal repertoires, and provides a quantitative basis for categorical perception and effective communication in this species. Structural constancy of a large proportion of syllable types in the population also is shown within and between breeding seasons. Differences in syllable type occurrence and repertoire composition found within males in the same breeding season may explain when they pair, and may have implications for determining syllable repertoire size in individual males. Differences in syllable type occurrence and repertoire composition found between song samples of different males in the same season and within males in successive years, provide scope for further work to gain a better idea about the biological significance of these differences. Shared syllable types found in the population together with distinctness and constancy of syllable type structure provide a basis for these types to function as part of the specific mate recognition system, which allows the recognition and bringing together of mating partners.

An important principle of my thesis is that fundamental problems of definition and description need to be resolved before hypotheses about biological significance can be formulated and tested. In line with this principle, syllables, their component elements, syllable types and the sequential structure of Sedge Warbler song are defined as objectively as possible in an accurate, transparent and verifiable way, after which their importance in Sedge Warbler communication is considered. This definition hopefully will enable and encourage repeatable

vi
empirical studies involving Sedge Warbler song structure, including further research to determine whether the defined features of song structure, function as suggested in the specific mate recognition system, female choice and individual recognition in this species.
Acknowledgements

I thank my partner, Annie, and the members of my family, especially my father, mother and brother, Peter, who have supported and encouraged me. I am eternally grateful to my sons, Simon and Ben who have shown great understanding and love for me during the course of my struggle for scientific rigour, honesty and integrity in my fields of research.

My friends Rosie Cooney, Jaco Greeff, Stephanie Koch, Andrew Molteno, Belinda Reyers, Trevor and Paul Richter and Martin Whiting created a friendly, relaxing and stimulating atmosphere.

My advisor, Professor Willem Ferguson provided an excellent environment for intellectual exploration and development. This environment included freedom, support, encouragement, guidance, thoughtful and thought-provoking responses to questions, ideas about data analysis, and computer programming expertise. He wrote the code for the cluster-analysis-MANOVA, multiple range test collation, inter-syllable duration analysis and song simulation programs which enhanced the quality of this thesis. Dr W. R. Rice (University of California, Santa Cruz) provided his sequential Bonferroni program on request.

Professor Clarke Scholtz, Head of the Department of Zoology and Entomology, was encouraging and patient during this long study.

Professor Jan Coetzee, Head of the Unit for Electron Microscopy and Micro-analysis made the Macintosh available for several years of spectrographic analysis. He also provided support and encouragement.

I thank Clive Catchpole for introducing me to the European Sedge Warbler and providing the opportunity of a PhD on aspects of the behavioural ecology of this species at Royal Holloway, University of London. The present study uses some of the sound recordings made during my PhD. An Overseas Research Scholarship and a Rondebosch Old Boys Overseas Scholarship provided financial assistance for the PhD, while a Pretoria University Bursary covered the fees during the first two years of the present study.

Experienced members of the Runnymede Ringing Group taught me the skills of ringing, bird measurement and assessment during my five-year stay in the UK. Phil Davies, an A-ringer from this group took a keen and active interest in my Sedge Warbler research.

Digital Acquisition of Sound Recordings

Qualitative Analysis

Quantitative Analysis

Statistical Methods

Results

General

Putative syllable types (PSTs) not split

PSTs kept separate although not differing significantly in MANOVA

PSTs merged

Reertoire size

Discussion

Qualitative analysis and the influence of subjectivity

Quantitative analysis - minimising the influence of subjectivity

Song sample duration and the determination of estimated syllable repertoire size

Implications of subjectivity and insufficient song sample duration
Temporal and acoustic frequency differences between syllable types – biological significance

Conclusion

4. Syllable Repertoire and Syllable Type Differences in the European Sedge Warbler, *Acrocephalus schoenobaenus*

Abstract

Introduction

Materials and Methods

Acquisition of sound recordings

Qualitative analysis of putative syllable types (PSTs)

Quantitative analysis of PSTs

Structural differences between PSTs among males

Structural differences within syllable types

Differences in syllable type occurrence

Differences in common and peculiar syllable types among males

Results

Structural Differences Between Syllable Types Among Males

Structural Constancy Within Syllable Types

Differences in Syllable Type Occurrence

Differences in Common and Peculiar Syllable Types Among Males

Discussion

Hypothesis 1 - At the population level, syllable repertoires of male Sedge Warblers are composed of syllable types, which differ qualitatively and quantitatively from one another in temporal and acoustic frequency characteristics

Hypothesis 2 - Structural constancy of syllable types among males and within males over time

Hypothesis 3 - Differences in syllable type occurrence among males and within males over time

Hypothesis 4 - A proportion of syllable types is shared in a population, while other syllable types are peculiar to individual males

Conclusion

Chapter 1

| Table 1 | Studies examining variation within and/or between song types in various species of songbirds. |
| Table 2 | Studies investigating how songbirds categorise conspecific songs or their parts or components compared to classifications developed by researchers. |
| Table 3 | Studies investigating aspects of acoustic communication in species of songbird that sing more continuously than species with definite, discrete songs. |

Chapter 2

| Table 1 | Summary results of single spectrum (Fourier) analysis of mean intersyllable duration/s, syllable rate and syllable type rate time series for males 1, 4, 5 and 9 over 10-min. of continuous, natural song, showing cyclical behaviour for each time series, but divergent periods within and among time series variables. |
| Table 2 | Summary results of the cross-spectrum analysis of syllable rate and syllable type rate time series for males 1, 4, 5 and 9 over 10-min. of continuous, natural song showing covariance over a wide range of periods with no clear pattern within and among males. |
| Table 3 | Kruskal-Wallis one-way ANOVA results showing a significant difference between the 10-min. song samples in males 1, 4, 5 and 9 in the medians of four different types of duration, and in syllable and syllable type rates. |
| Figure 1 | Spectrogram of a natural sequence of phrases, syllables and their component elements, and syllable types comprising the song of male 1. Examples of measurements of syllable duration, intersyllable duration, element duration and inter-element duration are shown that formed the basis of the quantitative analysis of continuous... |
song of males 1, 4, 5 and 9.

Figure 2  Syllables and elements, but not songs are revealed as basic discrete vocal units in frequency distributions of male 1's, 4's, 5's and 9's inter-syllable and inter-element durations.

Figure 3  Descriptive statistics of syllable duration, element duration, inter-syllable duration, inter-element duration, syllable rate and syllable type rate for males 1, 4, 5 and 9.

Figure 4  Plots of males 2 and 3 derived from simulations based on summary data from two of Catchpole's (1976) males with discrete songs, show areas of distinct stability at around 1 s that indicate the ranges of intervals between songs. Songs as distinct vocal units however, are not evident when minimum inter-syllable duration defining a song is plotted against the resulting number of songs for the entire ranges of inter-syllable duration in males 1, 4, 5 and 9. Kolmogorov-Smirnov two sample test results show differences (D-max) between the distributions of males 1, 4, 5 and 9 and Catchpole's (1976) males 2 and 3.

Figure 5  Representative snapshots of continuous song in each of the four males showing number of syllables/s, number of syllable types/s and mean inter-syllable durations/s.

Figure 6  Relationship between mean inter-syllable duration/s and syllable rate and syllable type rate for males 1, 4, 5 and 9's pooled data, showing that higher syllable and syllable type rates result in shorter intervals between syllables.

Figure 7  Syllable rate frequency distributions at syllable type rates 1 to 5 for the pooled data of males 1, 4, 5 and 9. Non-parametric multiple comparisons between syllable rates at syllable type rates 1 to 5 are shown.
