*Design of a vibration absorber for vibrating screens*
APPENDIX A

Mathematical model of a single D.O.F vibration absorber
The kinetic energy of the system in figure A.1 is given by equation A.1:

$$T = \frac{1}{2} \left( m_1 \dot{x}_1^2 + m_s \dot{x}_2^2 + I_c \dot{\theta}^2 \right)$$  \hspace{1cm} (A.1)$$

$I_c$ is the moment of inertia of the mass $m_s$ about its mass centre. The relation between $x_2$, $\theta$, and $x_1$ are given by equations A.2 and A.3 (refer to figure A.2):

$$x_2 = \left( 1 - \frac{R}{r} \right) x_1$$  \hspace{1cm} (A.2)

$$\theta \approx -\frac{x_1}{r}$$  \hspace{1cm} (A.3)

Substituting these relations in equation A.1 results in the following:

$$T = \frac{1}{2} \left( m_1 + \left( 1 - \frac{R}{r} \right)^2 m_s + \frac{I_c}{r^2} \right) \dot{x}_1^2$$  \hspace{1cm} (A.4)$$
From equation A.4 the kinetic term in the Lagrange's equations can be derived:

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_i} \right) = \left( m_i + \left(1 - \frac{R}{r} \right)^2 m_s + \frac{I_o}{r^2} \right) \ddot{x}_i \tag{A.5}
\]

The elastic energy is given by:

\[
V = \frac{1}{2} k_i x_i^2 \tag{A.6}
\]

From equation A.6 the potential energy term in the Lagrange's equations can be derived:

\[
\frac{\partial V}{\partial x_i} = k_i x_i \tag{A.7}
\]

The Rayleigh function is given by:

\[
R = \frac{1}{2} c_i \dot{x}_i^2 \tag{A.8}
\]

From equation A.8 the damping term in the Lagrange's equations can be derived:

\[
\frac{\partial R}{\partial \dot{x}_i} = c_i \dot{x}_i \tag{A.9}
\]

The complete equation of motion (A.11) can be formulated by substituting the expressions in Lagrange's equations (A.10) with those found in equations A.5, A.7 and A.9.

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_j} \right) - \frac{\partial T}{\partial x_j} + \frac{\partial V}{\partial x_j} = Q_j^{(a)} \quad j = 1, 2, ..., n \tag{A.10}
\]

\[
\left( m_i + m_s \left(1 - \frac{R}{r} \right)^2 + \frac{I_o}{r^2} \right) \ddot{x}_i + c_i \dot{x}_i + k_i x_i = F_0 \sin(\omega t) \tag{A.11}
\]

The frequency response of the system to a force can be found by substituting the assumed solution and its derivatives (A.12, A.13 and A.14) as well as the harmonic force (A.15) into the equation motion (A.11). The frequency response to a force \( F_j(t) = F_j(t \omega) \) is shown in equation A.16.

\[
x_j(t) = X_j e^{i \omega t} \tag{A.12}
\]

\[
\dot{x}_j(t) = i \omega X_j e^{i \omega t} \tag{A.13}
\]

\[
\ddot{x}_j(t) = -\omega^2 X_j e^{i \omega t} \tag{A.14}
\]

\[
f_j(t) = F_j e^{i \omega t} \tag{A.15}
\]

\[
X_1 = \frac{1}{-\omega^2 \left( m_i + m_s \left(1 - \frac{R}{r} \right)^2 + \frac{I_o}{r^2} \right) + i \omega c_i + k_i} F_1 \tag{A.16}
\]
The transmissibility will be defined in terms of forces. For this purpose the force transmitted by the spring \( (F_s) \), the damper \( (F_d) \) and the dynamic force of the absorber \( (F_a) \) must be calculated. The first two are simply given by equation A.17 and A.18:

\[
F_s = k_s x_i \\
F_d = c_d x_i
\]  
(A.17)  
(A.18)

The complete derivation of equation A.19 is shown in Appendix D.

\[
F_a = \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r^2} - \frac{I_o}{r^2} \right] \ddot{x}_i
\]  
(A.19)

The transmissibility is given in terms of the forces and as a function of frequency. Equations A.17 to A.19 are rewritten using equations A.12 to A.14 and added to arrive at the total force transmitted to the foundation. The force applied at mass \( m_1 \) is given by equation A.15. The transmissibility is therefore:

\[
\frac{F_2}{F_1} = \frac{k_i + i \omega c_i + \omega^2 \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r^2} - \frac{I_o}{r^2} \right]}{k_i + i \omega c_i - \omega^2 \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r^2} + \frac{I_o}{r^2} \right]}
\]

(A.20)

Equation A.20 can be non-dimensionalised as follows:

\[
|T_i| = \left[ 1 - \left( \frac{\omega}{\omega_n} \right)^2 \right]^{\frac{3}{2}} + \left[ 2 \zeta \frac{\omega}{\omega_n} \right]^{\frac{3}{2}}
\]

(A.21)

\[
\phi = \tan^{-1} \left( \frac{2 \zeta \frac{\omega}{\omega_n}}{1 - \left( \frac{\omega}{\omega_n} \right)^2} \right) - \tan^{-1} \left( \frac{2 \zeta \frac{\omega}{\omega_n}}{1 - \left( \frac{\omega}{\omega_n} \right)^2} \right)
\]

(A.22)
The following transmissibility plot of equation A.20 illustrates the effect of damping. The importance of low damping in the absorber is clearly evident.

![Transmissibility and Phase angle plots](image)

**Figure A.3 Transmissibility plot of equation A.20 with \( \omega_e = 1, \omega_x = 0.5 \)**

The aim of the absorber is to minimise the force transferred to the foundation. This will be achieved when the numerator in the transmissibility equation (A.20) is equal to zero:

\[
k_i + i \omega c_i + \omega^2 \left[ m \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_{a}}{r^2} \right] = 0
\]  

(A.21)

The non-trivial solution for the isolation frequency \( (c_i = 0) \) is:

\[
f_a = \frac{1}{2\pi} \sqrt{-\frac{k_i}{m \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_{a}}{r^2}}}
\]  

(A.22)

The response of the screen to the applied force after the addition of the absorber is of critical importance since it will influence its effective operation. The response of the screen is given by equation A.16. From this equation it is evident that the response of the screen will be influenced by the addition of an absorber. The effect must be minimised through proper choice of parameters and the applied force must be adjusted to compensate.
The following figure illustrates the forced response of the system. The response at the isolation frequency can be low.

Figure A.4. A typical response of mass $m$, due to force $F$, with $\omega_n = 1$, $\omega_a = 0.5$ and $\zeta = 0.1$

The natural frequency can be seen on the FRF plot. The plot also shows the response of the system at the anti-resonant frequency (the exact point of anti-resonance might not be clear). The undamped natural frequency for this single degree-of-freedom system is given by equation A.23:

$$f_n = \frac{1}{2\pi} \sqrt{\frac{k}{m_1 + m_s \left(1 - \frac{R}{r}\right)^2 + \frac{I_2}{r^2}}}$$  \hspace{1cm} \text{(A.23)}$$
Appendix B

Mathematical model of a two D.O.F. vibration absorber system
Appendix B – Mathematical model of a two D.O.F. vibration absorber system

Figure B.1 A 2 degree-of-freedom vibration absorber system

The kinetic energy of the system in figure B.1 is given by equation B.1:

\[ T = \frac{1}{2} \left( m_1 \ddot{x}_1^2 + m_2 \ddot{x}_2^2 + m_B \ddot{x}_3^2 + I_G \ddot{\theta}^2 \right) \]  \hspace{1cm} (B.1)

\( I_G \) is the moment of inertia of the mass \( m_B \) about its mass centre. The relation between \( x_3 \), \( \theta \), and \( x_2 \) are given by equations B.2 and B.3 (refer to figure B.2):

\[ x_3 = \left( 1 - \frac{R}{r} \right) x_2 \]  \hspace{1cm} (B.2)

\[ \theta \approx -\frac{x_2}{r} \]  \hspace{1cm} (B.3)

Figure B.2 Schematic of relationship between variables

The development of a vibration absorber for vibrating screens
Substituting these relations in equation B.1 results in the following:

\[
T = \frac{1}{2} \left[ m_i x_i^2 + \left( m_i + \left(1 - \frac{R}{r}\right)^2 m_b + \frac{I_a}{r^2}\right) x_i^2 \right] 
\] (B.4)

From equation B.4 the kinetic terms in the Lagrange's equations can be derived:

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_i} \right) = m_i \ddot{x}_i 
\] (B.5)

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) = \left( m_i + \left(1 - \frac{R}{r}\right)^2 m_b + \frac{I_a}{r^2}\right) \ddot{x}_2 
\] (B.6)

The elastic energy is given by:

\[
V = \frac{1}{2} \left( k_i (x_i - x_2)^2 + k_j x_j^2 \right) 
\] (B.7)

From equation B.7 the elastic terms in the Lagrange's equations can be derived:

\[
\frac{\partial V}{\partial x_i} = k_i x_i - k_j x_j 
\] (B.8)

\[
\frac{\partial V}{\partial x_2} = -k_i x_i + k_j x_j + k_2 x_2 
\] (B.9)

The Rayleigh function is given by:

\[
R = \frac{1}{2} \left( c_i (\dot{x}_i - \dot{x}_2)^2 + c_j \dot{x}_j^2 \right) 
\] (B.10)

From equation B.10 the damping terms in the Lagrange's equations can be derived:

\[
\frac{\partial R}{\partial \dot{x}_i} = c_i \dot{x}_i - c_j \dot{x}_2 
\] (B.11)

\[
\frac{\partial R}{\partial \dot{x}_2} = -c_i \dot{x}_i + c_j \dot{x}_2 + c_2 \dot{x}_2 
\] (B.12)

The mass matrix is given by equations B.5 and B.6:

\[
[M] = \begin{bmatrix} m_i & 0 \\ 0 & m_i + \left(1 - \frac{R}{r}\right)^2 m_b + \frac{I_a}{r^2} \end{bmatrix} 
\] (B.13)

The stiffness matrix is given by equations B.8 and B.9:

\[
[K] = \begin{bmatrix} k_i & -k_i \\ -k_i & k_1 + k_2 \end{bmatrix} 
\] (B.14)
The damping matrix is given by equations B.11 and B.12:

\[
[C] = \begin{bmatrix}
  c_i & -c_i \\
  -c_i & c_i + c_2
\end{bmatrix}
\]

(B.15)

The complete equation of motion (B.17) can be formulated by substituting the expressions in the Lagrange equation (B.16) with those found in equations B.5 and B.6, B.8 and B.9 and B.11 and B.12.

\[
\begin{bmatrix}
  m_1 \\
  0 
\end{bmatrix}
+ \left( 1 - \frac{R}{r} \right) ^2 m_2 + \frac{I_{\alpha}}{r^2}
\begin{bmatrix}
  \ddot{x}_1 \\
  \ddot{x}_2
\end{bmatrix}
+ \begin{bmatrix}
  c_i & -c_i \\
  -c_i & c_i + c_2
\end{bmatrix}
\begin{bmatrix}
  \dot{x}_1 \\
  \dot{x}_2
\end{bmatrix}
+ \begin{bmatrix}
  k_i & -k_i \\
  -k_i & k_i + k_2
\end{bmatrix}
\begin{bmatrix}
  x_1 \\
  x_2
\end{bmatrix}
= \begin{bmatrix}
  F_{\alpha} \sin(\omega t) \\
  0
\end{bmatrix}
\]

(B.16)

The frequency response of the system to a force vector can be found by substituting the assumed solution and its derivatives (A.12, A.13 and A.14) as well as the harmonic force (A.15) into the equation of motion (B.17). The frequency response to a force vector \( F(t) \) is shown in equation B.22.

\[
\begin{bmatrix}
  X_1 \\
  X_2
\end{bmatrix}
= \begin{bmatrix}
  -\omega^2 m_1 + i\omega c_i + k_i \\
  -i\omega c_i - k_i
\end{bmatrix}
\begin{bmatrix}
  -i\omega c_i - k_i \\
  i\omega c_i + k_i
\end{bmatrix}
\begin{bmatrix}
  F_1 \\
  F_2
\end{bmatrix}
\]

(B.17)

The response at \( m_2 \) can be found by calculating the inverse of the system matrix:

\[
F_1 = \frac{-a_{21}}{a_{11}a_{22} - a_{12}a_{11}}
\]

\[
= \frac{i\omega c_i + k_i}{(-\omega^2 m_1 + i\omega c_i + k_i)(-\omega^2 m_2 + m_2 \left( 1 - \frac{R}{r} \right)^2 + \frac{I_{\alpha}}{r^2}) + i\omega (c_i + c_2) + k_i + k_2 - (i\omega c_i + k_i)^2}
\]

(B.18)

The transmissibility will be defined in terms of forces. For this purpose the force transmitted by the spring \( (F_s) \), the damper \( (F_d) \) and the dynamic force of the absorber \( (F_a) \) must be calculated. The first two are given by equations B.19 and B.20:

\[
F_s = k_s x_2
\]

(B.19)

\[
F_d = c_2 \dot{x}_2
\]

(B.20)

The complete derivation of equation B.21 is shown in Appendix D.

\[
F_a = \left[ m_2 \left( 1 - \frac{R}{r} \right) \frac{R}{r} \frac{I_{\alpha}}{r^2} \right] \ddot{x}_2
\]

(B.21)
The transmissibility is given in terms of the forces and as a function of frequency. Equations B.19 to B.21 are rewritten using equations A.12 to A.14 and added to arrive at the total force transmitted to the foundation. The force applied at mass $m_j$ is given by equation B.18. The transmissibility is therefore:

$$\frac{F_2}{F_1} = \frac{k_z + i\omega c_z + \omega^2 \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_0}{r^2} \right]}{F_1} X_2$$

$$= \frac{\left( i\omega c_z + k_z \right) \left( k_z + i\omega c_z + \omega^2 \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_0}{r^2} \right] \right)}{\left( -\omega^2 m_s + i\omega c_z + k_z \right) \left( -\omega^2 \left[ m_s + m_g \left( 1 - \frac{R}{r} \right)^2 + \frac{I_0}{r^2} \right] + i\omega \left( c_z + c_s \right) + k_s + k_z \left( i\omega c_z - k_z \right) \right)}$$

(B.22)

The following transmissibility plot of equation B.26 illustrates the effect of $c_2$. The importance of low damping in the absorber is clearly evident.

![Transmissibility plot](image)

Figure B.3 A typical transmissibility plot of equation B.26 showing the effects of damping ($c_1 = 0, c_2 = 0.01, m_g = 0.5, m_s = m_2 = k_1 = k_2 = 1$ and $R/r = 2$)
The aim of the absorber is to minimise the force transferred to the foundation. This will be achieved when the numerator in the transmissibility equation (B 22) is equal to zero:

\[ k_2 + i\omega c_2 + \omega^2 \left[ m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_o}{r^2} \right] = 0 \]  
(B.23)

The non-trivial solution for the undamped isolation frequency \((c_2 = 0)\) is:

\[ f_a = \frac{1}{2\pi} \frac{-k_2}{\sqrt{m_s \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I}{r^2}}} \]  
(B.24)

The response of the screen to the applied force after the addition of the absorber is of critical importance since it will influence its effective operation. The response of the screen is given by equation B.25. From this equation it is evident that the response of the screen will be influenced by the addition of an absorber. The effect must be minimised through proper choice of parameters and the applied force must be adjusted to compensate.

\[
\frac{X_1}{F_1} = \frac{a_{22}}{a_{11}a_{22} - a_{21}a_{12}} = \frac{-\omega^2 \left[ m_2 + m_s \left( 1 - \frac{R}{r} \right)^2 + \frac{I_o}{r^2} \right] + i\omega(c_1 + c_2) + k_1 + k_2}{(-\omega^2m_1 + i\omega c_1 + k_1) - \omega^2 \left[ m_2 + m_s \left( 1 - \frac{R}{r} \right)^2 + \frac{I_o}{r^2} \right] + i\omega(c_1 + c_2) + k_1 + k_2} \]  
(B.25)

The following plot of equation B.25 illustrates the forced response of the system at mass \(m_1\).
The natural frequencies can be seen on both figure B.4 and B.5. The figures also show the response of the system at the isolation frequency (the exact point of isolation might not be clear). The natural frequencies cannot easily be found analytically but are rather calculated numerically with an eigenvalue approach.

The following plot of equation B.18 illustrates the forced response of the system at mass $m_2$. The 2 degree-of-freedom model can be used to model a screen mounted on an absorber.
Figure B.5 A typical response of mass $m_2$ due to force $F_1$ $(\alpha_{21})$
with $c_1 = 0$, $c_2 = 0.01$, $m_0 = 0.5$, $m_1 = m_2 = k_1 = k_2 = 1$ and $R/r = 2$
APPENDIX C

Mathematical model of a 3 D.O.F. vibration absorber system
Appendix C – Mathematical model of a 3 D.O.F. vibration absorber system

Figure C.1 A three degree-of-freedom system including a vibration absorber

The kinetic energy of the system in figure C.1 is given by equation C.1:

\[ T = \frac{1}{2} \left( m_1 \dot{x}_1^2 + m_2 \dot{x}_2^2 + m_3 \dot{x}_3^2 + m_4 \dot{\theta}^2 + I_0 \dot{\theta}^2 \right) \]  

(C.1)

\( I_0 \) is the moment of inertia of the mass \( m_B \) about its mass centre. The relation between \( x_4 \), \( \theta \), \( x_2 \) and \( x_3 \) are given by equations C.2 and C.3 (refer to figure C.2):

\[ x_4 = \left( 1 - \frac{R}{r} \right) x_2 + \frac{R}{r} x_3 \]  

(C.2)

\[ \theta \approx \frac{x_3 - x_2}{r} \]  

(C.3)

Figure C.2. Schematic of relationship between variables
Substituting these relations in equation C.1 results in the following:

\[
T = \frac{1}{2} \left[ m_1 \ddot{x}_1 + \left( m_2 + \left( 1 - \frac{R}{r} \right)^2 m_g + \frac{I_g}{r^2} \right) \ddot{x}_2 + \left( m_3 + \left( \frac{R}{r} \right)^2 m_g + \frac{I_g}{r^2} \right) \ddot{x}_3 + \left( 2 \left( \frac{1 - \frac{R}{r}}{r} \right) \left( \frac{R}{r} \right) m_g - 2 \frac{I_g}{r^2} \right) \ddot{s} \right]
\]  
(C.4)

From equation C.4 the kinetic terms in the Lagrange's equations can be derived:

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_1} \right) = m_1 \ddot{x}_1 \]  
(C.5)

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_2} \right) = \left( m_2 + \left( 1 - \frac{R}{r} \right)^2 m_g + \frac{I_g}{r^2} \right) \ddot{x}_2 + \left( \left( 1 - \frac{R}{r} \right) \frac{R}{r} m_g - \frac{I_g}{r^2} \right) \ddot{x}_3 \]  
(C.6)

\[
\frac{d}{dt} \left( \frac{\partial T}{\partial \dot{x}_3} \right) = \left( m_3 + \left( \frac{R}{r} \right)^2 m_g + \frac{I_g}{r^2} \right) \ddot{x}_3 + \left( \left( 1 - \frac{R}{r} \right) \frac{R}{r} m_g - \frac{I_g}{r^2} \right) \ddot{s} \]  
(C.7)

The elastic energy is given by:

\[
V = \frac{1}{2} \left( k_1 (x_1 - x_2)^2 + k_2 (x_2 - x_3)^2 + k_3 x_3^2 \right) \]  
(C.8)

From equation C.8 the elastic terms in the Lagrange's equations can be derived:

\[
\frac{\partial V}{\partial x_1} = k_1 x_1 - k_1 x_2 \]  
(C.9)

\[
\frac{\partial V}{\partial x_2} = -k_1 x_1 + k_1 x_2 + k_2 x_2 - k_2 x_3 \]  
(C.10)

\[
\frac{\partial V}{\partial x_3} = -k_2 x_2 + k_2 x_3 + k_3 x_3 \]  
(C.11)

The Rayleigh function is given by:

\[
R = \frac{1}{2} \left( c_1 (\dot{x}_1 - \dot{x}_2)^2 + c_2 (\dot{x}_2 - \dot{x}_3)^2 + c_3 \dot{x}_3^2 \right) \]  
(C.12)

From equation C.12 the damping terms in the Lagrange's equations can be derived:

\[
\frac{\partial R}{\partial \dot{x}_1} = c_1 \dot{x}_1 - c_1 \dot{x}_2 \]  
(C.13)

\[
\frac{\partial R}{\partial \dot{x}_2} = -c_1 \dot{x}_1 + c_1 \dot{x}_2 + c_2 \dot{x}_2 - c_2 \dot{x}_3 \]  
(C.14)

\[
\frac{\partial R}{\partial \dot{x}_3} = -c_2 \dot{x}_2 + c_2 \dot{x}_3 + c_3 \dot{x}_3 \]  
(C.15)
The mass matrix is given by equations C.5, C.6 and C.7:

\[
[M] = \begin{bmatrix}
  m_1 & 0 & 0 \\
  0 & m_2 + \left(1 - \frac{R}{r}\right)^2 m_3 + \frac{I_0}{r^2} & -\frac{R}{r} \left(1 - \frac{R}{r}\right) \frac{I_0}{r^2} \\
  0 & \left(1 - \frac{R}{r}\right) \frac{R}{r} \frac{I_0}{r^2} m_3 + \frac{R}{r} \left(1 - \frac{R}{r}\right) \frac{I_0}{r^2} & m_3 + \frac{I_0}{r^2}
\end{bmatrix} \tag{C.16}
\]

The stiffness matrix is given by equations C.9, C.10 and C.11:

\[
[K] = \begin{bmatrix}
  k_1 & -k_2 & 0 \\
  -k_2 & k_1 + k_2 & -k_2 \\
  0 & -k_2 & k_1 + k_3
\end{bmatrix} \tag{C.17}
\]

The damping matrix is given by equations C.13, C.14 and C.15:

\[
[C] = \begin{bmatrix}
  c_1 & -c_2 & 0 \\
  -c_2 & c_1 + c_2 & -c_2 \\
  0 & c_2 & c_2 + c_3
\end{bmatrix} \tag{C.18}
\]

The complete equation of motion (C.20) can be formulated by substituting the expressions in the Lagrange's equations (A.10) with those found in equations C.5 to C.7, C.9 to C.11 and C.13 to C.15:

\[
[M][\ddot{x}] + [C][\dot{x}] + [K][x] = \{f\} \tag{C.20}
\]

The frequency response of the system to a force vector can be found by substituting the assumed solution and its derivatives (A.12, A.13 and A.14) as well as the harmonic force (A.15) into the equation of motion (C.20). The frequency response to a force vector \(F(t) = \{0\}\) is shown in equation C.25.

The transmissibility is calculated numerically from equations C.21 and C.22

\[
\begin{bmatrix}
  X_1 \\
  X_2 \\
  X_3
\end{bmatrix} = \left(-\omega^2[M] + i\omega[C] + [K]\right)^{-1}\begin{bmatrix}
  F_1 \\
  F_2 \\
  F_3
\end{bmatrix} \tag{C.21}
\]

\[
T_y = \left|\frac{X_1}{X_3}\right| \tag{C.22}
\]

The following transmissibility plot \((T_{31})\) described by equation C.22 illustrates the effect of \(c_2\). The importance of low damping in the absorber is clearly evident. It is not always possible to see all the natural frequencies on the transmissibility plot. The position of the natural frequency is however extremely important and will be discussed later in this appendix.
Appendix C – Mathematical model of a 3 D.O.F. vibration absorber system

Figure C.3 A typical transmissibility plot of equation C.22 \(T_{zz} \) showing the effects of damping
\[ c_1 = c_3 = 0, \ m_B = 0.5, \ m_2 = k_2 = 1, \ I_0 = 0 \text{ and } R/r = 2 \]

In order to be able to formulate an expression for the isolation frequency, an analytical expression will be found for the transmissibility between mass \( m_2 \) and mass \( m_3 \). Equation C.23 was found by substituting the assumed solution and its derivatives (A.12, A.13 and A.14) in the 3rd equation of the set of equations described by equation C.20.

\[
\frac{X_3}{X_2} = \frac{k_z + i\omega c_2 + \omega^2 \left( m_3 \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_0}{r^3} \right)}{k_z + k_2 + i\omega(c_2 + c_3) - \omega^2 \left( m_3 + m_2 \left( \frac{R}{r} \right)^2 + \frac{I_0}{r^3} \right)} \quad (C.23)
\]

The aim of the absorber is to minimise the force transferred to the foundation by minimising the motion of mass \( m_3 \). This will be achieved when the numerator in the transmissibility equation (C.23) is equal to zero:

\[
k_z + i\omega c_2 + \omega^2 \left( m_3 \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_0}{r^3} \right) = 0 \quad (C.24)
\]

The non-trivial solution for the undamped isolation frequency \( c_2 = 0 \) is:

\[
f_a = \frac{1}{2\pi} \sqrt{-\frac{k_z}{m_3 \left( 1 - \frac{R}{r} \right) \frac{R}{r} - \frac{I_0}{r^3}}} \quad (C.25)
\]
The response of the screen to the applied force after the addition of the absorber is of critical importance since it will influence its effective operation. The response of the screen is given by equation C.21. From this equation it is evident that the response of the screen will be influenced by the addition of an absorber. The effect must be minimised through proper choice of parameters and the applied force must be adjusted to compensate.

The following figures show the response at mass \( m_1 \) and \( m_3 \) due to a force acting on mass \( m_1 \). The three natural frequencies are clearly visible. The figures also show the response of the system at the anti-resonant frequency. Figure C.6 shows that mass \( m_3 \) has low response at anti-resonance.

The 3 DOF model can be used to model a screen mounted on an absorber when the stiffness of the support must be taken into account.
Figure C.5 The response of mass $m_1$ due to force $F_1$ ($\alpha_{11}$)
($c_1 = c_2 = 0$, $c_2 = 0.01$, $m_B = 0.5$, $m_1 = m_2 = m_3 = k_1 = k_2 = k_3 = 1$, $I_G = 0$ and $R/r = 2$)

Figure C.6 The response of mass $m_1$ due to force $F_1$ ($\alpha_{31}$)
($c_1 = c_2 = 0$, $c_2 = 0.01$, $m_B = 0.5$, $m_1 = m_2 = m_3 = k_1 = k_2 = k_3 = 1$, $I_G = 0$ and $R/r = 2$)

The development of a vibration absorber for vibrating screens
APPENDIX D

Analysis of the inertial absorber force
The sum of the moments about fixed pivot C is given by:

\[ \Sigma M_c = I_c \alpha \]
\[ = -Fr \quad \text{(D.1)} \]

The sum of the forces in the x and y directions are:

\[ \Sigma F_x = -m_s a_x \]
\[ R_x = -m_s (R - r)\omega \]
\[ \Sigma F_y = m_s a_y \]
\[ F + R_y = m_s (R - r)\alpha \quad \text{(D.3)} \]

The trigonometric relationship between the linear and angular acceleration is given by:

\[ \ddot{x} \approx -r \alpha \quad \text{(D.4)} \]

By substituting equation D.1 in equation D.3 the force \( R_y \) can be found as a function of the angular acceleration:

\[ R_y = m_s (R - r)\alpha + \frac{I_c}{r} \alpha \quad \text{(D.5)} \]

The angular acceleration can now be substituted with the relationship given by equation D.4:

\[ R_y = \frac{m_s}{r} (R - r)\ddot{x} - \frac{I_c}{r^2} \dddot{x} \quad \text{(D.6)} \]
The following expression can be written for the moment of inertia about C using Steiner’s theorem:

$$I_c = m_s (R - r)^2 + I_o$$  \hspace{1cm} (D.7)

Substituting this relationship into equation D.6 results in:

$$R_s = \left[ -\frac{m_s}{r} (R - r) - \frac{m_s (R - r)^2}{r^2} - \frac{I_o}{r^2} \right] \ddot{x}$$

$$= \left[ m_s \left(1 - \frac{R}{r}\right) \frac{R}{r} - \frac{I_o}{r^2} \right] \ddot{x}$$  \hspace{1cm} (D.8)
APPENDIX E

Computational fluid dynamics analysis
E.1. Introduction

Viscous damping is a damping force that is proportional to the velocity of the fluid. To find the force it is necessary to solve the shear force on the port wall and the pressure drop across the port. Analytical equations that describe both these quantities were discussed in chapter 2, but they exist only for simple geometries. To find the total force acting on the port used in the final design computational fluid dynamics had to be used. The objective was to compare the final design with the theoretical model in order to show that a smooth inlet will reduce the amount of damping. The force found from the analytical equations was compared to CFD results for the theoretical case. This gave confidence in the method. The force acting on the port used in the final design was solved using CFD and compared to the theoretical case. This was a qualitative study and showed a marked improvement in the damping when a smooth inlet/outlet geometry was used.

E.2. Method and Model parameters

Computational fluid dynamics produce a prediction of how fluid will flow for a given situation (Shaw, 1992). To do this the numerical solutions to the equations that govern the flow must be solved. These equations can be found from the knowledge that mass and momentum must be conserved. The package used to solve the flow was STAR-CD. This package uses the finite volume method to solve the equations for the fluid flow, which is described in detail by Patankar (1980). Turbulence was included in the model using the $k-\varepsilon$ turbulence model. This method calculates the kinetic energy $k$ and the distribution of the dissipation rate of $k$ denoted by $\varepsilon$.

The inputs needed by the CFD package are:
- the geometry of the flow domain including the computational mesh
- fluid properties
- boundary conditions
- solution control parameters

Due to its simplicity, the geometry for the theoretical model was created in STAR-CD. The geometry for the design was imported from CAD. A mesh of hexahedral cells was created. Only $1/8^{th}$ of the port was modeled to reduce the solution time. The fluid properties were the same for both models.
Table E.2 Fluid properties

<table>
<thead>
<tr>

<td>1000</td>
</tr>
<tr>
<td>Absolute viscosity</td>
<td>1×10$^{-3}$</td>
</tr>
</tbody>
</table>

The boundary condition was treated as a constant axial velocity inlet at the bottom and a constant axial velocity outlet at the top. It was assumed that the fluid flow would have the same velocity as the port that is forcing it. The port is moving relative to the sleeve and it is therefore possible to specify the boundary condition on the sleeve and keep the port fixed.

The velocity of the port is equal to the inlet velocity and is related to the amplitude and circular frequency by:

$$\dot{x}(t) = i\omega x e^{i\omega t}$$

By solving the damping for different inlet velocities, a lookup table can be constructed. For a fixed amplitude the damping coefficient is only a function of frequency.

The SIMPLE algorithm was used for the solution. The solution converged in 3000 iterations. The $y^+$ values were checked and fell within the acceptable range of 30 to 100.

The following two paragraphs will give detailed results for the two models. Graphical output of the CFD program is also included to give physical insight in the processes that cause damping.

E.3. Theoretical model

Figures E.1 to E.3 show the grid of hexahedral cells. A constant axial velocity outlet boundary condition was specified at the top and a constant axial velocity inlet at the bottom. The walls had a no-slip boundary condition. A symmetry plane was defined to reduce the size of the model. No flow is allowed perpendicular to this plane.

The port inlet and outlet are sudden contractions and expansions, which will create the maximum flow losses for this port and reservoir diameter.
Figure E.1 3D grid for 1/8th of the flow region

Figure E.2 Grid at the outlet

Design of a vibration absorber for vibrating screens
E.4 Relative pressure

On figure E.4 it can be seen that the flow separation at the inlet cause a pressure drop at the wall. The flow separation reduces the effective flow area, which accelerates the fluid. This condition can be seen in figure E.5 and E.7.
The wall had a no-slip boundary condition the effect of which can be seen in figure E.5.

E.5 Velocity magnitude

Re-circulation at the outlet is caused by flow separation as can be seen in figure E.6. This condition will increase the damping.
E.7 Velocity vectors at the inlet

Figure E.8 Total pressure drop ($\Delta p_t$) as a function of port velocity ($v_p$)

The total pressure drop is shown in figure E.8. The pressure drop at the outlet is shown in figure E.10 and is clearly much more that predicted analytically. The reason for this is the proximity of the boundary.
Figure E.9 The pressure drop at the outlet ($\Delta p_o$) as a function of port velocity ($\dot{x}$)

Figure E.10 The pressure drop at the inlet ($\Delta p_i$) as a function of port velocity ($\dot{x}$)
Figure E.11 Force in the z-direction ($F_z$) as a function of port velocity ($\dot{x}$)

Figure E.12 Damping ($c$) as a function of port velocity ($\dot{x}$)

The pressure varies quadratically as can be expected from its relation with velocity (figure E.13) while the damping coefficient varies linearly as can be seen in figure E.12.

Design of a vibration absorber for vibrating screens
E.4. Design

Figure E.13 3D grid for 1/8th of the flow region

Figure E.14 Grid at the outlet
The mesh used for the final design is shown in figures E.13 to E.15. The boundary condition was a constant velocity in the z-direction on the ends of the grid. Figure E.16 show that the gradual change in area causes less flow disturbance.
Appendix E – Computational fluid dynamics analysis

Figure E.17 Velocity magnitude

Figure E.18 Velocity vectors at outlet

Figures E.17 and E.18 show that the flow still gets separated at the outlet where a recirculation region develops causing backward flow in the outlet. This will increase the damping. At the inlet (figure E.19) hardly any separation occurs.
Figure E.19 Velocity vectors at inlet

Figure E.20 The pressure drop at the inlet ($\Delta p_0$) as a function of port velocity ($\bar{x}$)

Figure E.20 shows that the pressure drop at the inlet is far less than for square inlets/outlets. The pressure drop decrease at the outlet is not as dramatic (figure E.21).

Design of a vibration absorber for vibrating screens
Figure E.21 The pressure drop at the outlet ($\Delta p_o$) as a function of port velocity ($\bar{v}$)

Figure E.22 Total pressure drop ($\Delta p_t$) as a function of port velocity ($\bar{v}$)

Figure E.22 shows that changes to the inlet/outlet geometry can have a major impact on the total pressure drop.
Figure E.23 Force in the z-direction ($F_z$) as a function of port velocity ($\dot{x}$)

Figure E.24 Viscous damping ($c$) as a function of port velocity ($\dot{x}$)

The conical inlets/outlets reduced the viscous damping significantly as can be seen in figure E.24.
E.5. Conclusion

The CFD analysis proved to be worthwhile. The total pressure drop of the design is 2.5 times less than the theoretical model. The viscous damping coefficient is 5 times less. The design was done only with knowledge based on theory and empirical data and further improvements are therefore possible. Manufacturability also played a major role in the eventual choice of geometry. The port geometry can however be optimized using CFD. Optimization of the port geometry could significantly reduce damping further and is recommended for a future study.
