Portal hypertension;
Portosystemic shunt

Abstract
The scrotal varicocele is a common finding encountered during clinical examination. A porto-systemic shunt presenting with an associated varicocele is exceptionally rarely reported. Herein, we report such a case in an HIV positive man who presented with bilateral varicoceles. This is only the fifth case of such an association in the world literature. A literature review and the possible underlying pathophysiological mechanisms of this rare association are expanded further.

Introduction
A varicocele is defined as an abnormal tortuosity and dilatation of the testicular veins and pampiniform plexus. This may be present due to absent or incompetent valves, or increased hydrostatic pressure [1]. The left-sided varicocele is much more common (up to 90%) than the right-sided variant [1]. Varicoceles found in relation to porto-systemic shunting is theoretically possible, but are exceptionally rarely reported. Herein, we report such a case in a newly diagnosed HIV positive man with an underlying protein-S deficiency.

abdominal varices (Fig. 2A & B). Bilateral testicular varicoceles were also detected.

Haematological investigations revealed an acquired protein-S deficiency, which was discovered to be secondary to a newly diagnosed concurrent HIV infection. He did not have evidence of any AIDS defining disease at the time of presentation. This thrombophilic state resulted in splenic and portal vein thrombosis.

Multiple enlarged, tortuous collateral vessels were noted in the retroperitoneum with the left testicular vein draining into this venous plexus inferior to the left kidney (Fig. 2).

Although the right testicular vein drained directly into the inferior vena cava, this patho-physiological mechanism involved in this right-sided varicocele may be explained by the increase in hydrostatic pressure caused by the porto-systemic shunt, or by extrinsic compression from the conglomerate of collateral veins (Fig. 2).

Our index patient defaulted from follow up, further investigations and refused further treatment.

**Discussion**

Patients with underlying portal hypertension and a porto-systemic shunt rarely present with a right-sided or bilateral varicocele. A Pubmed search (with cross referencing) using the search terms; ‘varicocele AND portal hypertension’ and ‘varicocele AND porto-systemic shunt’ only revealed the following four previously reported cases (Table 1) [1–4].
Various presenting symptoms have been previously described, including a scrotal mass, hydrocele, hernia or infertility [1–4]. The underlying diagnosis in these patients may go undetected to the ‘unassuming Urologist’. On palpation of a varicocele, the scrotal examination may feel like a ‘bag of worms’ [5], we have now shown that the search for the underlying cause in a bilateral/right-sided varicocele, may be metaphorically similar to ‘opening the can of worms’ to reveal a sometimes sinister underlying diagnosis.

Conclusion

This case further illustrates the possibility of considering the underlying cause in (atypical) or bilateral varicoceles. The presence of a right-sided varicocele may also reveal an underlying renal cell carcinoma, retroperitoneal fibrosis or associated tumour [5]. With this report we have illustrated another rare association which may present with bilateral varicoceles; portal hypertension with a porto-systemic shunt.
