Psychological management intervention guidelines for rape survivors with post-

traumatic stress disorder (PTSD): A brief exploratory systematic literature review

Abstract

This exploratory systematic literature review aimed to characterise the current evidence on

psychological management intervention guidelines for use with rape survivors with post-

traumatic stress disorder (PTSD) symptoms. For the data searches we accessed the following

electronic databases: Google Scholar, Science Direct, EBSCOhost, and PsychInfo. We utilised

search terms with variations of the following key words: psychological management guidelines

of PTSD*, rape survivors*. Inclusion criteria were guidelines for rape survivors with PTSD

that consider referral, treatment, and preventive and health promotion in an international

setting. We excluded guidelines that did not address PTSD resulting from rape in an

international setting. We employed a narrative synthesis data analysis approach to integrate the

evidence from across studies. Findings suggest prevalent guidelines for rape survivors with

PTSD focus on cognitive behavioural therapy and other psychological management

interventions in highly specialised areas and Primary Health Care (PHC) settings in

international countries, but not in other countries such as South Africa. Emerging guidelines

are needed for PTSD psychological management interventions in rape care clinics situated in

South Africa.

Keywords: psychological management interventions or guidelines of PTSD, rape survivors

1

Introduction

The experience of sexual rape is a significant factor contributing to Post Traumatic Stress Disorder (PTSD) (Masho & Ahmed, 2007; Ullman, Filipas, Townsend & Starzynski, 2007; Klump, 2006; Breslau, 2000). Global prevalence estimates for PTSD among rape survivors range from 17.3% in Australia (Creamer, Burgess & McFarlane, 2001) to about 76% in the United States of America (USA) (Littleton & Henderson, 2009). In South Africa (SA), PTSD among rape survivors is estimated at around 21.3% (Nöthling, Lammers, Martin & Seedat, 2015). The use of psychological management interventions to treat PTSD resulting from rape experiences is universal. However, what is sorely lacking is evidence of the types of guidelines currently used and the treatment care or other survivor support interventions that are intended. In particular, there is a lack of evidence on stated or implied guidelines from settings in African countries. This exploratory systematic review aims to summarize the evidence on psychological management interventions for health professionals working with rape survivors who exhibit PTSD symptoms.

Goal of this study

We utilised an exploratory systematic review applied to the following items: (i) Were the appropriate stakeholders involved in the development of the guidelines? (ii) Are the groups to which guidelines apply or do not apply clearly stated? (iii) Is potential bias eliminated and what is the validity of the guidelines? (iv) What is the level of supporting evidence identified for each recommendation? (see also Newhouse, Dearholt, Poe, Pugh and White, 2007). As such, this study aimed to summarise the evidence on psychological management guidelines for use by professionals working with PTSD among rape survivors. Psychological management

guidelines are important for benchmarking evidence-based standards of care to manage PTSD post the rape experience.

Methods

Search procedure

We searched from the following databases for relevant publications from 2000 to 2018: Google Scholar, Science Direct, EBSCOhost, Psych info, Medline JSTOR, and South African sources such as the National Department of Health (NDoH) website. The first listed author did the initial search and reviewed the guidelines to assess if they met the Population, Intervention, Comparison, Outcome and Time frame (PICOT) (Riva, Malik, Burnie, Endicott & Busse, 2012) strategy and clinical practice guideline appraisal criteria (Newhouse, Dearholt, Poe, Pugh & White, 2007). Then the reviewed guidelines were interrogated by the second listed author to confirm if those guidelines adopted psychological management interventions to lessen the symptoms of PTSD as experienced by rape survivors. A total of 1090 articles and guidelines were found in the initial search. However, after a rigorous process of selection using the inclusion criteria, only four guidelines were finally accepted for review as reflected in Figure 1.

Inclusion criteria

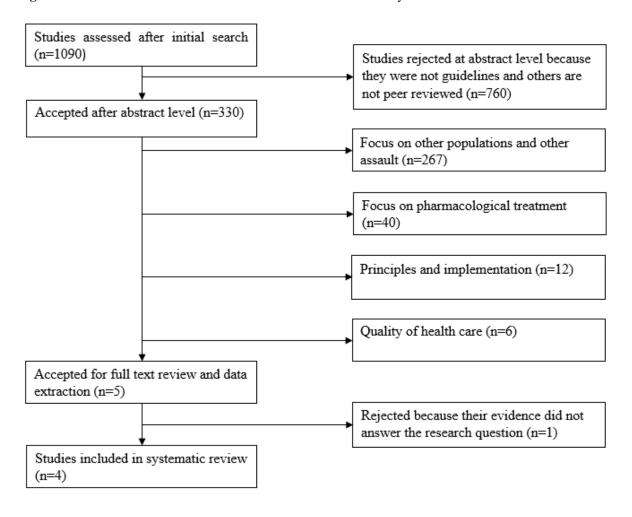

The inclusion criteria were publications that explicitly addressed referral, treatment, preventive and health promotion guidelines for the psychological management of PTSD within African countries or an African cultural heritage and internationally following rape experiences.

Moreover, the guidelines had to be written in English and used as the current treatment guidelines of the country or context concerned.

Exclusion criteria

This study excluded publications which did not describe referral, treatment, and preventive and health promotion guidelines for rape survivors with PTSD in an international setting.

Figure 1. Selection Process for Studies Included and Excluded in the Systematic Review

Data analysis

We utilized the critical appraisal process tool Newhouse et al (2007) to summarize the evidence. In using the tool, we considered the extent to which the guidelines applied to psychological management of PTSD in rape survivors across the domains of care: referral, treatment, and preventive and health promotion. See Table 1 for a summary of the studies included.

Results and Discussion

The results of this review support those of numerous studies (Foa, Keane, Friedman, & Cohen,

2008; Resick, Nishith and Griffin, 2003; Shubina 2005; Posmontier, Dovydaitis and Lipman 2010; Bisson, Ehlers, Matthews, Pilling, Richards and Turner, 2007; Kirkpatrick and Heller, 2014), which illustrated that individual trauma focused-CBT, exposure therapy, Eye Movement Desensitization and Reprocessing (EMDR), provision of Selective Serotonin Reuptake Inhibitors (SSRIs), supportive interviews and psychological management interventions adopted among the guidelines stated in Table 1 could be used to lessen PTSD symptoms post rape experiences.

The results of this review illustrated that group trauma focused CBT has less effect on PTSD management after a rape experience than other interventions, and this result differs from that of Bisson et al (2007) who illustrated that group CBT is effective in managing PTSD post rape experiences. In addition, as indicated in Table 1, the results of this review share the same views as Forbes, Creamer, Phelps, Bryant, McFarlane, Devilly and Newton (2007); Bisson and Andrew (2009); Ramchandani and Jones (2003), because they illustrated that non-directive therapy, psychodynamic therapy and systemic psychotherapy are less effective in managing PTSD post rape experience.

However, the evidence of effectiveness of these aforementioned psychological management interventions in these guidelines mostly comes from studies conducted in the USA. This clearly shows that there is a lack of guidelines specific to African settings or contexts, hence there is no evidence of the available PTSD psychological management interventions post rape experiences. Despite that, South Africa for example, reports among the highest rape incidences annually world-wide (South African Police service, 2017) and this means that survivors of rape might be prone to PTSD without evidence of how it is assessed, managed or treated because of a lack of context-specific guidelines for PTSD psychological management interventions. Therefore, this clearly shows that there is a need for the development of guidelines for PTSD psychological management interventions specific to the African context as well as to test their effectiveness in order to provide holistic care for rape survivors.

Conclusion

There are no specific guidelines that can be used by health care practitioners to assess, manage, and treat PTSD postrape experiences in rape care clinics situated in South African settings We recommend the development of South African context specific psychological management interventions guidelines that will be used to manage PTSD post-rape experiences in order to optimise treatment and rehabilitation care of rape survivors.

Limitations and recommendations

This review only focused on PTSD psychological management interventions, and as such, it cannot be generalised to other psychological problems associated with rape experiences Furthermore, our study findings must be understood with the limitation that the effectiveness of psychological management interventions in these guidelines were based on studies conducted in the USA and UK There is a need for documentation testing of guidelines specific to South African settings or contexts South Africa, for example, annually reports among the highest rape incidences world-wide (South African Police service, 2017) Furthermore, 74 5% of rape survivors in a specific region of South Africa were diagnosed with PTSD (Sepeng & Makhado, 2018) This indicates that survivors of rape are prone to PTSD without evidence of how it is assessed, managed or treated in rape care clinics situated in South Africa This study is a small instalment towards understanding the lack of PTSD psychological management interventions in Africanist settings against an international background.
