Box 524, Auckland Park, Johannesburg, South Africa; ${ }^{2}$ Department of Plant and Soil Sciences, University of Pretoria, Private Bag X20, Hatfield, Pretoria, 0028, South Africa. * Correspondence: E-mail: idubery@uj.ac.za; Tel.: +27-11-559-2401.

Fig. S1: Symptom development in tomato leaves harvested at different time points following inoculation with Phytophthora capsici zoospores. Leaf wilting started on day 2 and progressed over time, and at day 8 the tomato leaves were completely wilted.

Figure S2: Eight days post-infection comparison between P. capsici-infected and control tomato plants.
(A): Zoospore inoculated plant with arrow indicating infection and necrosis at the inoculation site and
(B): Control plant with arrow pointing to a Ventti filter wrapped around the inoculation site. (Section 4.1).

Figure S3: Representative BPI MS chromatograms of extracts from tomato plants infected with
Phytophthora capsici; leaf tissue. Base peak mass chromatograms displaying comparative chromatographic differences in different time points: non-treated (NT, days 2 and 8 ) and P. capsici (PC, days 2, 4, 6 and 8 ) infected. Visual inspection of the chromatograms evidently shows differential peak populations, for instance in the 4-20 min chromatographic region. (A): ESI negative mode and (B): ESI positive mode.

Figure S4: Representative BPI MS chromatograms of extracts from tomato plants infected with Phytophthora capsici; stem tissue. Base peak mass chromatograms displaying comparative chromatographic differences in different time points: (i) non-treated (NT, days 2 and 8 ) and (ii) P. capsici (PC, days 2, 4, 6 and 8) infected. Visual inspection of the chromatograms evidently shows differential peak populations, for instance in the 4-20 min chromatographic region. (A): ESI negative mode and (B): ESI positive mode.

Figure S5: Representative BPI MS chromatograms of extracts from tomato plants infected with Phytophthora capsici; root tissue. Base peak mass chromatograms displaying comparative chromatographic differences in different time points: (i) non-treated (NT, days 2 and 8 ) and (ii) P. capsici (PC, days 2, 4, 6 and 8 ) infected. Visual inspection of the chromatograms evidently shows differential peak populations, for instance in the 4-20 min chromatographic region. (A): ESI negative mode and (B): ESI positive mode.

Figure S6: Unsupervised statistical analysis of extracts from tomato plants infected with Phytophthora capsici; leaf data acquired in ESI ${ }^{+}$mode. (A): A PCA scores scatter plot of all the samples, including the QC samples, colored according to time points. The PCA model presented here was a 7-component model, with $\mathrm{R}^{2}$ of 0.697 and $Q^{2}$ of 0.645 . (B): The HCA dendrogram corresponding to (A). Unsupervised statistical analysis is used to generate subgrouping of samples based on similar observations in (A) while the HCA dendrogram shows the hierarchical relationship between samples (B).

Figure S7: Unsupervised statistical analysis of extracts from tomato plants infected with Phytophthora capsici; stem data acquired in ESI ${ }^{-}$mode. (A): A PCA scores scatter plot of all the samples, including the QC samples, colored according to time points. The PCA model presented here was a 7-component model, with $\mathrm{R}^{2}$ of 0.804 and $Q^{2}$ of 0.752. (B): The HCA dendrogram corresponding to (A). Unsupervised statistical analysis is used to generate subgrouping of samples based on similar observations in (A) while the HCA dendrogram shows the hierarchical relationship between samples (B).

Figure S8: Unsupervised statistical analysis of extracts from tomato plants infected with Phytophthora capsici; stem data acquired in ESI ${ }^{+}$mode. (A): A PCA scores scatter plot of all the samples, including the QC samples, colored according to time points. The PCA model presented here was a 7-component model, with $\mathrm{R}^{2}$ of 0.835 and $\mathrm{Q}^{2}$ of 0.783 . (B): The HCA dendrogram corresponding to (A). Unsupervised statistical analysis is used to generate subgrouping of samples based on similar observations in (A) while the HCA dendrogram shows the hierarchical relationship between samples (B).

Figure S9: Unsupervised statistical analysis of extracts from tomato plants infected with Phytophthora capsici; root data acquired in ESI mode. (A): A PCA scores scatter plot of all the samples, including the QC samples, colored according to time points. The PCA model presented here was a 7-component model, with $\mathrm{R}^{2}$ of 0.759 and $Q^{2}$ of 0.640 . (B): The HCA dendrogram corresponding to (A). Unsupervised statistical analysis is used to generate subgrouping of samples based on similar observations in (A) while the HCA dendrogram shows the hierarchical relationship between samples (B).

Figure S10: Unsupervised statistical analysis of extracts from tomato plants infected with Phytophthora capsici; root data acquired in ESI ${ }^{+}$mode. (A): A PCA scores scatter plot of all the samples, including the QC samples, colored according to time points. The PCA model presented here was a 7 -component model, with $\mathrm{R}^{2}$ of 0.788 and $Q^{2}$ of 0.692 . (B): The HCA dendrogram corresponding to (A). Unsupervised statistical analysis is used to generate subgrouping of samples based on similar observations in (A) while the HCA dendrogram shows the hierarchical relationship between samples (B).

Figure S11: OPLS-DA modeling and variable/feature selection of extracts from tomato plants infected with Phytophthora capsici; leaf data acquired on ESI ${ }^{+}$mode. (A): A typical OPLS-DA score plot separating nontreated (NT) day 8 plants vs. $P$. capsici $(\mathrm{PC})$-treated day 6 plants $\left(1+1+0\right.$ components, $\mathrm{R}^{2} \mathrm{X}=0.741, \mathrm{Q}^{2}=0.998$, CV-ANOVA $p$-value $\left.=7.96 \times 10^{-15}\right) .(\mathbf{B})$ : An OPLS-DA loadings $\mathbf{S}$-plot for the same model in (A); only variables with the correlation $[(p($ corr $)] \geq|0.6|$ and covariance $(p 1) \geq|0.5|$ were chosen as discriminating variables and identified using the $m / z$ to generate elemental composition. (C): A variable importance for the projection (VIP) plot for the same model, pointing mathematically to the importance of each variable in contributing to group separation in the OPLS-DA model. (D): A typical variable trend plot (of the selected variable in VIP and S-plots), displaying the changes of the selected variables across the samples (NT day $8 v s$. PC day 6 ). This shows that the selected features significantly discriminate the treated from the control samples.

Figure S12: OPLS-DA modeling and variable/feature selection of extracts from tomato plants infected with Phytophthora capsici; stem data acquired on ESI mode. (A): A typical OPLS-DA score plot separating nontreated (NT) day 8 plants vs. P. capsici $(\mathrm{PC})$-treated day 6 plants $\left(1+1+0\right.$ components, $\mathrm{R}^{2} \mathrm{X}=0.817, \mathrm{Q}^{2}=0.999$, CV-ANOVA $p$-value $=3.19 \times 10^{-20}$ ). $(\mathbf{B})$ : An OPLS-DA loadings S-plot for the same model in (A); only variables with the correlation $[(p(c o r r)] \geq|0.6|$ and covariance $(p 1) \geq|0.5|$ were chosen as discriminating variables and identified using the $m / z$ to generate elemental composition. (C): A variable importance for the projection (VIP) plot for the same model, pointing mathematically to the importance of each variable in contributing to group separation in the OPLS-DA model. (D): A typical variable trend plot (of the selected variable in VIP and S-plots), displaying the changes of the selected variables across the samples (NT day 8 vs . PC day 6). This shows that the selected features significantly discriminate the treated from the control samples.

Figure S13: OPLS-DA modeling and variable/feature selection of extracts from tomato plants infected with Phytophthora capsici; stem data acquired on ESI ${ }^{+}$mode. (A): A typical OPLS-DA score plot separating nontreated (NT) day 8 plants vs. $P$. capsici $(\mathrm{PC})$-treated day 6 plants $\left(1+1+0\right.$ components, $\mathrm{R}^{2} \mathrm{X}=0.855, \mathrm{Q}^{2}=0.995$, CV-ANOVA $p$-value $\left.=3.9 \times 10^{-18}\right) .(\mathbf{B})$ : An OPLS-DA loadings S-plot for the same model in $(\mathbf{A})$; only variables with the correlation $[(p(c o r r)] \geq|0.6|$ and covariance $(p 1) \geq|0.5|$ were chosen as discriminating variables and identified using the $\mathrm{m} / \mathrm{z}$ to generate an elemental composition. (C): A variable importance for the projection (VIP) plot for the same model, pointing mathematically to the importance of each variable in contributing to group separation in the OPLS-DA model. (D): A typical variable trend plot (of the selected variable in VIP and S-plots), displaying the changes of the selected variables across the samples (NT day $8 v s$. PC day 6). This shows that the selected features significantly discriminate the treated from the control samples.

Figure S14: OPLS-DA modeling and variable/feature selection of extracts from tomato plants infected with Phytophthora capsici; root data acquired on ESI- mode. (A): A typical OPLS-DA score plot separating nontreated (NT) day 8 plants vs. P. capsici $(\mathrm{PC})$-treated day 6 plants $\left(1+1+0\right.$ components, $\mathrm{R}^{2} \mathrm{X}=0.677, \mathrm{Q}^{2}=0.998$, CV-ANOVA $p$-value $\left.=9.48 \times 10^{-16}\right) .(\mathbf{B}):$ An OPLS-DA loadings $\mathbf{S}$-plot for the same model in $(\mathbf{A})$; only variables with the correlation $[(p($ corr $)] \geq|0.6|$ and covariance $(p 1) \geq|0.5|$ were chosen as discriminating variables and identified using the $m / z$ to generate an elemental composition. (C): A variable importance for the projection (VIP) plot for the same model, pointing mathematically to the importance of each variable in contributing to group separation in the OPLS-DA model. (D): A typical variable trend plot (of the selected variable in VIP and S-plots), displaying the changes of the selected variables across the samples (NT day 8 vs . PC day 6). This shows that the selected features significantly discriminate the treated from the control samples.

Figure S15: OPLS-DA modeling and variable/feature selection of extracts from tomato plants infected with Phytophthora capsici; root data acquired on ESI ${ }^{+}$mode. (A): A typical OPLS-DA score plot separating nontreated (NT) day 8 plants vs. P. capsici $(\mathrm{PC})$-treated day 6 plants $\left(1+1+0\right.$ components, $\mathrm{R}^{2} \mathrm{X}=0.742, \mathrm{Q}^{2}=0.996$, CV-ANOVA $p$-value $\left.=1.08 \times 10^{-15}\right) .(\mathbf{B})$ : An OPLS-DA loadings $\mathbf{S}$-plot for the same model in (A); only variables with the correlation $[(p($ corr $)] \geq|0.6|$ and covariance $(p 1) \geq|0.5|$ were chosen as discriminating variables and identified using the $m / z$ to generate an elemental composition. (C): A variable importance for the projection (VIP) plot for the same model, pointing mathematically to the importance of each variable in contributing to group separation in the OPLS-DA model. (D): A typical variable trend plot (of the selected variable in VIP and S-plots), displaying the changes of the selected variables across the samples (NT day 8 vs . PC day 6). This shows that the selected features significantly discriminate the treated from the control samples.

Table S1: Summary of annotated (MSI-level 2) metabolites that contributed to the discriminating variability in the altered metabolomes of root -, stem - and leaf tissue of tomato plants infected with Phytophthora capsici (as described by chemometric models). These discriminating metabolites were identified based on OPLS-DA Splots, with a rigorous statistical validation (as explained in the text - Figure 4). These reported metabolites had VIP scores > 1.0 .

Note: The table only shows the identified metabolites in the various tissue. For differential reprogramming and tissue-specific metabolites, please refer to the correlation analysis (Figure 5) and VIP score-plots (Figure 6).

Figure S16: Correlation matrix among the changes ( $\Delta$ ) within/between extracts from stems of non-treated (NT) day 8 tomato plants and Phytophthora capsici (PC)-treated day 6 plants. Metabolite-metabolite correlations among identified molecules were obtained by deriving a Pearson correlation coefficient. Red indicates a positive correlation, and blue indicates a negative correlation. Abbreviations are explained in Table S1. Dendrograms are shown on the top and left of the correlation, indicating clustering of positive and negative correlations.

Figure S17: Correlation matrix among the changes ( $\Delta$ ) within/between extracts from roots of non-treated (NT) day 8 tomato plants and Phytophthora capsici (PC)-treated day 6 plants. Metabolite-metabolite correlations among identified molecules were obtained by deriving a Pearson correlation coefficient. Red indicates a positive correlation, and blue indicates a negative correlation. Abbreviations are explained in Table S1. Dendrograms are shown on the top and left of the correlation, indicating clustering of positive and negative correlations.

Table S2: One-way ANOVA comparing mean values of quantified aromatic amino acids and phytohormones in various tissue of tomato plants infected with Phytophthora capsici.
