## The Gendered Impacts of IMF Programs and IMF-Recommended Tax Reforms on Labour Market Outcomes in Ghana

### Abstract

**Purpose** – This paper examines whether or not gender disparity exists in labour market outcomes during IMF austerity programs with tax conditionality.

**Design/Methodology/Approach** – Annual time series data on the Ghanaian economy from 1990 to 2023 is used. The empirical strategies are the Autoregressive Distributed Lag bounds test and the Two-Stage Least Squares Instrumental Variable techniques.

**Findings** - The main findings indicate that the unemployment gap between women and men widens during IMF programs, especially when tax conditionality is imposed. The evidence also suggests that, besides widening the labour force participation gap, the decline in labour force participation of women is more pronounced than that of men during IMF programs. However, stronger democratic regimes can help reduce these negative effects on women's participation.

**Practical implications** - To address Sustainable Development Goal (SDG) 5, which aims to achieve gender equality and empower women, policymakers may need to incorporate gender considerations into public policy formulation. Particularly, gender indicators must be incorporated in the performance metrics during program design. Additionally, disaggregated data on gendered labour market outcomes must be collected and analyzed appropriately to inform policy.

**Originality/value** –This paper presents a unique case for developing countries, particularly in the Ghanaian context, due to the frequency and multiplicity with which IMF bailouts are sought. Besides focusing on unemployment and labour force participation gaps as outcome variables, gendered disaggregated data and interactive regressions are also employed to enhance the depth of the analysis.

## 1. Introduction

The International Monetary Fund (IMF) is obligated to conduct annual Article IV surveillance in member countries, where policy advice is prescribed on fiscal and monetary issues. Governments of developing countries, particularly, turn to the IMF when they require a bailout to stabilize their balance of payments operations. However, the IMF bailout, which may ultimately help to restore macroeconomic stability, is not without conditionality. Most governments are asked to implement radical spending cuts, phase out subsidy schemes, and reform some tax schemes (Reinsberg et al., 2020). Accordingly, to create fiscal space and reduce tax evasion, most developing countries reform their tax systems by shifting from trade and corporate taxes to consumption taxes (Bastiaens & Rudra, 2018; Reinsberg et al., 2020). The IMF's prescription for most countries facing balance of payment challenges is to shift towards broad-based consumption taxes. A key feature of this advice is to adopt or adjust the Value Added Tax (VAT) base (Buenaventura & Miranda, 2017; Dunno et al., 2024). Thus, the IMF is known to be very instrumental in the introduction of VAT in most countries, and empirical evidence shows revenue increases during IMF programs (Reinsburg et al., 2020).

The VAT, which is applied at every stage of the production chain and computed based on the value added to a product, is considered effective in generating more revenue for the government than sales tax. It is also broad-based, covering persons in the informal sector. However, consumption-based taxes that include VAT are regressive, affect marginalized groups, and in some cases are gender insensitive (Kunawotor et al., 2021). Detraz and Peksen (2016) suggest that IMF austerity measures disproportionately affect women's economic empowerment. Following a similar line of reasoning, ActionAid (2024) argues that IMF tax reforms disproportionately affect women, exacerbate gender disparities, and inadvertently undermine economic stability and growth. Also, Asai and Zhang (2023) argue that cuts in essential social spending reduce women's labour force participation. With specific reference to VAT, Donno et al. (2024) present empirical evidence of the adverse effect of IMF-induced VAT imposition on the life chances of women in developing countries. Baer and Williams (2023) argue that taxes create economic and social inequalities in women's economic participation. Similarly, Buenaventura and Miranda (2017) assert that VAT is regressive for lower earners, among whom women, particularly those in wage employment or the informal sector, are disproportionately represented. The above discussion suggests that women are more disadvantaged during economic crises because they engage in

1  
2  
3 vulnerable employment than men. That notwithstanding, IMF programs, which are associated  
4 chiefly with contractionary fiscal policies, adversely affect the labour market outcomes of women.  
5

6  
7 The interest in undertaking this study is sparked by Ghana's recent program with the IMF,  
8 where the country secured a US\$3 billion Extended Credit Facility (ECF) arrangement in May  
9 2023. At about the same time, the VAT rate was increased by 2.5%, from 12.5% to 15%. In  
10 addition, poverty levels continue to rise, with close to one-quarter of Ghanaians (23.4%)  
11 wallowing in poverty, of which women are the worst hit (Adjei-Mantey & Kunawotor, 2024).  
12 Additionally, the labour force participation rate for women in Ghana lags behind that of men, and  
13 the unemployment rate for women is higher. For example, the modeled ILO estimate of the labour  
14 force participation rate for men in 2023 is 72.45%, while that for women is 65.27%. Similarly, the  
15 unemployment rate for women is 0.7 percentage points higher than that of men (World Bank,  
16 2024). Figure 1 depicts the gender dimensions of unemployment in Ghana. The global gender gap  
17 index, compiled by the World Economic Forum (2024), also ranks Ghana 88<sup>th</sup> out of 146 countries.  
18 The IMF (2022; 2013a) posits that emerging evidence suggests that economic growth increases  
19 when more women participate in the labour force. The IMF acknowledges gender inequality as a  
20 macrocritical issue, where gender disparity can undermine macroeconomic stability (ActionAid,  
21 2024). The Fund also concurs that mainstreaming and narrowing gender gaps fall within its  
22 mandate. Accordingly, they instituted a gender strategy document outlining how the IMF can assist  
23 its member countries in addressing gender disparities while fulfilling its core functions of  
24 surveillance, lending, and capacity development (IMF, 2022). The strategy document, they note,  
25 is timely given the current economic uncertainties and recent shocks, which are exacerbating pre-  
26 existing gender gaps. However, these have not been practically incorporated into its recent lending  
27 program to Ghana.

42

43 To further the frontiers of knowledge in this grey area, incorporating Goal 5 of the SDGs,  
44 which seeks to achieve gender equality, we test the assertions mentioned above by providing first-  
45 hand empirical econometric evidence in the Ghanaian case. Accordingly, we not only examine the  
46 impact of being under an IMF program in general, but we also investigate the unintended  
47 consequences of IMF conditionality, specifically through VAT imposition and adjustments, on  
48 gender equality. In other words, do VAT imposition and adjustments during IMF programs widen  
49 the unemployment gap between women and men? What effects does it have on women's labour  
50 force participation? This study complements the extant literature in several ways. First, we  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 primarily focus on labour market outcomes by computing the unemployment gap and labour force  
4 participation gap as key outcome variables. These two outcome variables capture key  
5 socioeconomic metrics of gender inequality, besides gender disparity being pervasive in women's  
6 labour market outcomes (Kern et al., 2024).  
7  
8  
9

10 Additionally, the World Economic Forum (2024) posits that these outcome variables  
11 capture essential dimensions of women's economic empowerment. The IMF (2024) also suggests  
12 that reforms aimed at addressing gender inequality in labour force participation can yield gains  
13 comparable to those of pro-growth structural reforms. Second, although the unemployment and  
14 labour force participation gaps capture the differential impact of IMF programs on women, we  
15 additionally use the female and male labour force participation rates and unemployment rates as  
16 gender-disaggregated outcomes. Third, unlike existing studies that focus on the general effects of  
17 IMF programs, this study focuses on the impacts of IMF tax conditionality through VAT  
18 imposition and adjustment, in addition to an IMF program. Fourth, we gauge the interactive effects  
19 of IMF programs and democracy on labour market outcomes. Fifth, we address potential  
20 endogeneity between IMF programs and labour market outcomes by instrumenting IMF tax  
21 conditionality programs with natural disasters. Sixth, we provide a novel experience through a case  
22 study of Ghana, which is a suitable case study due to the frequency and multiplicity with which  
23 IMF bailouts are sought. The remainder of this paper is structured to include a review of gender  
24 inequality in Ghana, a **theoretical and empirical literature review**, the methodology, and a  
25 discussion of the results. It ends with some policy suggestions and directions for future research.

## 39 **2. Gender Inequality in Ghana**

40  
41 This section is divided into three subsections. The first presents some relevant statistics on gender  
42 inequality in Ghana. The second discusses the relationship between government economic policy,  
43 the IMF's role, and gender inequality in Ghana. The final part analyzes the impact of the gender  
44 gap on economic performance.  
45  
46  
47  
48

### 49 ***Statistics on the Gender Gap in Ghana***

50  
51 Government economic policy reforms, even when well-intentioned, can increase or hinder  
52 economic participation in different ways. For instance, labour market policies, tax reforms, and  
53 welfare programs can create unequal opportunities for men and women (ActionAid, 2024). The  
54 outcome of government policies is observed in the recent statistics below. Thus, a detailed current  
55  
56  
57  
58  
59  
60

1  
2  
3 statistic on the gender gap in Ghana is presented in Table 1. The labour force participation gap in  
4 2024 shows a deficit of 3.26%, indicating that more males participate in the labour market than  
5 females. There are also 0.64% more unemployed females than males.  
6  
7

8 Furthermore, male legislators, senior officials, and managers outnumber their female  
9 counterparts by 11.46%. This is concerning given that the representation of women in managerial  
10 positions is positively correlated with firm performance (IMF, 2022). Additionally, greater gender  
11 balance in senior positions enhances the diversity of thought and fosters checks and balances,  
12 ultimately contributing to greater stability and profitability (IMF, 2024). Professional and technical  
13 male workers also exceed their female counterparts by 16.66%. Females in Ghana also earn \$2,930  
14 less than males, indicating persistent income inequality, as observed in other African economies  
15 (Kunawotor et al., 2022; 2020). Low-income limits women's access to essential services, including  
16 healthcare, education, and housing. These points reinforce the argument that females have fewer  
17 economic opportunities than males.  
18  
19  
20  
21  
22  
23  
24

25 The statistics on educational outcomes are not significantly different from those in the labour  
26 market. Besides enrollment in secondary school, where gender parity exists, females are  
27 underrepresented in the other educational categories. This is evident in the higher male-to-female  
28 ratios in primary school enrollment and tertiary education. Consequently, 3% more males graduate  
29 from tertiary institutions.  
30  
31  
32  
33

34 Gender disparity is also pronounced in national-level political representation. The male  
35 representation in parliament exceeds that of females by a staggering 70.8%. Similarly, there are  
36 65.52% more men in ministerial positions than women. This adversely affects economic  
37 development, as noted that women in political leadership are associated with higher infrastructure  
38 spending and female educational attainment (IMF, 2024; 2022). The trend of statistics clearly  
39 shows the depth of women's marginalization in Ghana.  
40  
41  
42  
43

### 45 ***Government Economic Policies, Role of IMF, and Gender Inequality in Ghana***

46 Ghana has a complex history of economic policies that predates independence. Due to some of  
47 these non-transforming economic policies, the country has resorted to the IMF for Standby  
48 arrangements and extended credit facilities multiple times to support its economic agenda,  
49 primarily towards restoring macroeconomic stability. Accordingly, the IMF has been a principal  
50 advisor to Ghana in shaping economic and tax policy during periods of economic distress. To  
51 improve revenue generation, tax efficiency, and broaden the tax base, the IMF team recommends  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 a spectrum of reforms as inputs in their deliberations with the Ghanaian government. Key among  
4 them was the introduction and periodic increases in the VAT. These policies have been quite  
5 effective in closing the fiscal space, particularly in revenue generation, but are mostly associated  
6 with concerns over socio-economic and gender inequality. Equity is often sacrificed for the sake  
7 of efficiency and macroeconomic stability. For example, there are no specific tax reliefs for low-  
8 income earners and women in the informal sector, which limits the effectiveness of promoting  
9 inclusive growth (ActionAid, 2024).  
10  
11  
12  
13  
14

15 IMF (2022) argues that mainstreaming gender at the Fund begins by acknowledging that  
16 reducing gender disparity is linked to higher economic growth, economic stability, and lower  
17 income inequality. They argue that emergent evidence indicates economic growth rises when more  
18 women participate in the labour force. However, economic and financial policies can either  
19 exacerbate or reduce gender inequality; hence, they need to be well-designed and structured. The  
20 IMF has instituted a gender strategy outlining how the Fund can assist its member countries in  
21 addressing gender disparities while fulfilling its core functions of surveillance, lending, and  
22 capacity development. The IMF proposed four key pillars in its maiden gender strategy document  
23 (IMF, 2022). The first entails collecting gender-disaggregated data and developing modelling tools  
24 for policy analysis. The second seeks to develop a robust governance framework based on the  
25 macrocriticality of gender. The third strategy aims to strengthen collaboration with external  
26 partners to benefit from knowledge sharing and peer learning, and the final one is to ensure the  
27 efficient use of resources allocated to gender by establishing a central unit to realize scale  
28 economies and support country teams.

35  
36  
37  
38

39 Despite the recognition of gender issues as critical to macroeconomic stability and  
40 development of a strategy document in this respect, the recent IMF program in Ghana is deficient  
41 in mainstreaming gender sensitive issues. There are no targeted policies to address gender  
42 inequalities, and no evidence of discussions on how this program affects men and women  
43 differently. The practical implementation of the gender strategy to Ghana's tax structure is missing,  
44 hence these issues remain at the theoretical level. The disparity between men and women in the  
45 labour market, income levels, and asset ownership continues to widen, as shown in Table 1. Gender  
46 disparity creates unequal access to resources and opportunities, hindering women's economic  
47 participation. It limits women's ability to benefit from and contribute to growth. It is instructive to  
48

3 note that the IMF discussed incorporating gender issues into its surveillance program a decade ago  
4 (IMF, 2013b).  
5  
6

### 7 ***Macrocriticality of the Gender gap/The impacts of the Gender gap on economic performance***

8 Gender disparity is harmful to economic growth and development. For instance, gender gaps  
9 indicate that productive human resources are underdeveloped, underemployed, and/or  
10 misallocated, which adversely affects productivity and growth (IMF, 2024). Where the burden of  
11 macroeconomic adjustment disproportionately falls on women, children's education suffers  
12 because women tend to invest more in their children's education than men (Doepke & Tertilt,  
13 2019). Additionally, monetary policy intervention through higher interest rates reduces women's  
14 access to credit and impacts their economic participation. A lower gender gap is thus associated  
15 with reduced income inequality, improved social stability, and economic growth (IMF, 2022).  
16 Furthermore, reducing gender gaps can improve the economy's resilience to shocks and enhance  
17 the prospective balance of payments stability by increasing competitiveness and the variety of  
18 goods countries produce and export.  
19  
20  
21  
22  
23  
24  
25  
26  
27

28 IMF (2022) identified the following as the main drivers of the gender gap: unequal access to  
29 education, health services, infrastructure, assets, and technology; unequal legal rights; violence  
30 against women; unequal distribution of unpaid care and domestic work between men and women;  
31 and cultural factors. Accordingly, to narrow the gender gap in developing countries, the Fund  
32 argues that economic policies should focus on investing in education, health, and infrastructure.  
33 Policies should also be directed towards increasing financial inclusion and reducing legal barriers.  
34 Furthermore, policies addressing unpaid care work, flexible work arrangements, parental leave,  
35 and tax disincentives for secondary earners must be critically evaluated.

### 44 **3. Theoretical and Empirical Literature**

45 This section is divided into two sections. The first is a theoretical review, and the second is an  
46 empirical review. The empirical literature review is further compartmentalized into two sections.  
47 The first discusses the nexus between IMF programs and gender outcomes. The second section  
48 addresses the relationship between IMF tax conditionality and gendered outcomes.

### ***Theoretical Review***

The theory regarding the nexus between IMF programs and gender disparity can be viewed from the perspective of feminist economics. This theory introduces gender concerns into the assumptions of traditional economics, arguing that gender plays a significant role in an individual's participation in economic activities. The theory critiques traditional economics for limiting the definition of production activities to paid work in the market, while unpaid household work is classified under consumption (Kamal, 2022). Feminist theory argues that the domestic tasks performed by women, such as childbearing, elderly care, or household chores, contribute to the household's income by saving or providing unpaid care services necessary for the home's sustainability. Consequently, the traditional definition of production underestimates the significance of women's non-remunerated work and their contribution to household income. The theory emphasizes the limitations the patriarchal nature of domestic work creates, as it places the majority of the unpaid care work burden on females, affecting their ability to participate in the paid labor market activities due to limited time (Paltasingh & Lingam, 2014).

Consistent with this study, the feminist economics theory highlights the gender disparity created in developing countries as they participate in structural adjustment programs. The austerity measures imposed by lending institutions, such as the IMF, are associated with public spending cuts, tax increases, and the removal of subsidies to achieve macroeconomic stability. This, however, fails to recognize the disproportionate adverse impacts on women. For instance, consumption cuts reduce public spending on female-dominated sectors like health and education, increasing women's unpaid care burden and entrenching gender-based power imbalances that limit women's access to resources and decision-making. It also compels women to allocate more of their time to unpaid care services, restricting their participation in the labour market.

### ***IMF Program and Gender Outcomes***

In a recent study, Kern et al. (2024) examined the consequences of IMF austerity and liberalization policies on women's labour market outcomes in 128 developing countries from 1992 – 2018. The findings suggest that IMF programs, particularly during periods of economic turbulence, exacerbate existing gender inequalities. Thus, IMF programs have a negative impact on the unemployment gap, suggesting that women are more adversely affected by these programs than men. Reinsberg et al. (2023) investigated the role of women's leadership in the gendered consequences of IMF programs in 95 countries from 2000 to 2018. They find that the gendered

1  
2  
3 impacts of IMF programs are more pronounced for women when an all-men cabinet implements  
4 IMF reforms. However, when women ministers are in cabinet, these effects are lessened with a  
5 higher employment rate for women. They argue that the significance of women in leadership  
6 positions lies in their ability to mitigate the adverse effects of IMF programs. A while back, Detraz  
7 and Peksen (2016) assessed the impact of IMF programs on women's economic and political rights  
8 from 1981 - 2004 in a cross-country evidence that includes 119 low- and middle-income countries.  
9 The result shows women's economic rights deteriorate during IMF involvement, while no such  
10 effect is observed for political rights. The studies catalogued above suggest that women are  
11 disadvantaged when IMF programs are in place compared to their male counterparts.  
12  
13  
14  
15  
16  
17  
18  
19

### 20 *VAT, IMF Tax Conditionality and Gender Equality*

21 In the second group of studies, Donno et al. (2024), using panel data that cover 141 countries from  
22 1980 – 2019, estimate the effects of IMF programs with tax conditionality on women's labour  
23 force participation, education enrollment rates, and cardiovascular disease. The results show that  
24 under the IMF program with tax conditionality, women exhibit lower labour force participation,  
25 higher unemployment, and lower tertiary school enrollment. Adverse outcomes are noticed in the  
26 areas of economic activity, educational enrollment, and cardiovascular diseases for women's life  
27 chances when VAT is instrumented with IMF tax programs. Similarly, Buenaventura and Miranda  
28 (2017) provide an overview of the impact of IMF advice on tax reforms, mainly VAT, poverty,  
29 women's rights, and gender equality. They argue that the VAT that the IMF consistently insists  
30 should be adopted by developing countries in raising revenue is plagued with unending criticism,  
31 which relates to its regressivity, weighs heavily on poor women, and has gender discriminatory  
32 elements that adversely affect women. Maisonnave and Mamboundou (2022) conducted a gender  
33 analysis of tax reforms in Burkina Faso using a computable general equilibrium model (CGE) and  
34 simulation. The result shows that VAT reforms undermine household welfare, gender equality,  
35 and increase poverty.  
36  
37  
38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 Similarly, but in South Africa, Escalante et al. (2021) show how fiscal reforms that include a VAT  
50 increase affect women's labour market outcomes and poverty levels. Accordingly, they find that  
51 an increase in VAT increases poverty among female-headed households than male-headed ones.  
52 Specifically, they find that fiscal reforms increase the unemployment rates of women and lower  
53 their income levels and purchasing power.

## 4. Methodology

### 4.1 Data and Estimation Technique

An annual time series data on the Ghanaian economy from 1990 to 2023 is used. The data is sourced from the World Bank's World Development Indicators, Laeven and Valencia (2018), and Polity 5. The Autoregressive Distributed Lag (ARDL) bounds testing approach is used to estimate the model. Among other reasons, the ARDL is better suited to small samples (Haug, 2002). It is also useful irrespective of the order of integration, such as  $I(0)$  or  $I(1)$  (Pesaran et al. 2001). In addition, the Two-Stage Least Squares (2SLS) instrumental variable design addresses inherent endogeneity concerns related to IMF programs and labour market outcomes.

### 4.2 Empirical Model and Variable Measurement

The generic form of the empirical model underlying this paper is specified as follows;

$$y_t = \alpha_0 + \alpha_1 IMFTax_t + \alpha_2 X_t + u_t \quad (1)$$

Where  $y_t$  denotes measures of gender inequality, which is the outcome variable.  $IMFTax$  represents tax policy reforms under IMF programs in Ghana over the years. The "X" represents the vector of control variables that influence gender outcomes. Explicitly, the long-run and short-run error correction models are specified respectively as follows;

$$y_t = \alpha_0 + \sum_{i=1}^p \alpha_1 y_{t-i} + \sum_{i=0}^p \alpha_2 IMFTax_{t-i} + \sum_{i=0}^p \alpha_3 GDPpc_{t-i} + \sum_{i=0}^p \alpha_4 INF_{t-i} + \sum_{i=0}^p \alpha_5 FIN_{t-i} + \sum_{i=0}^p \alpha_6 DEM_{t-i} + u_t \quad (2)$$

$$\Delta y_t = \alpha_0 + \sum_{i=1}^p \alpha_1 \Delta y_{t-i} + \sum_{i=0}^p \alpha_2 \Delta IMFTax_{t-i} + \sum_{i=0}^p \alpha_3 \Delta GDPpc_{t-i} + \sum_{i=0}^p \alpha_4 \Delta INF_{t-i} + \sum_{i=0}^p \alpha_5 \Delta FIN_{t-i} + \sum_{i=0}^p \alpha_6 \Delta DEM_{t-i} + \eta_t ECT_{t-1} + u_t \quad (3)$$

To evaluate the gendered impact of IMF programs and tax policies, different dependent variables are used to measure gender inequality in the labour market. These are the unemployment gap and labour force participation gap. A similar approach was used by Kern et al. (2024). The

1  
2  
3 unemployment gap is calculated as the difference in unemployment rates between men and  
4 women, expressed as a ratio of the total unemployment rate. Formally, the unemployment gap ( $y^U$ )  
5 is calculated as  $y^U = \frac{U_M - U_F}{U} * 100$ , where  $U_M$  represents the unemployment rate of men or males.  
6  
7  
8  $U_F$  represents the unemployment rate of women or females, while  $U$  represents the total  
9 unemployment rate, which is the sum of the men's and women's values.  
10  
11

12  
13 It should be noted that the unemployment rate of women is subtracted from the men's value, given  
14 that unemployment is a negative outcome. Hence, a higher value of the unemployment gap  
15 indicates relatively less unemployment among women. The unemployment rate indicates the  
16 number of unemployed individuals as a percentage of the total economically active population in  
17 the labour force. The male or female unemployment rate is the share of males or females in the  
18 labour force who are unemployed or seeking employment. The data is sourced from the World  
19 Bank's World Development Indicators.  
20  
21  
22  
23  
24

25  
26 The second outcome variable used is the labour force participation (LFP) gap. Like the  
27 unemployment gap, the LFP gap is computed as the difference in labour force participation  
28 between women and men as a ratio of the total labour force participation rate. Formally, the labour  
29 force participation gap ( $y^P$ ) is calculated as  $y^P = \frac{P_F - P_M}{P} * 100$ , where  $P_F$  represents the female  
30 labour force participation.  $P_M$  and  $P$  represent the male and total labour force participation rates,  
31 respectively. The labour force participation rate indicates the percentage of all working-age people  
32 who are either employed or actively seeking work. Hence, higher values of the LFP gap indicate  
33 relatively more female participation in the labour force. In addition to the unemployment and  
34 labour force participation gap as outcome variables, gender-disaggregated labour market data is  
35 used. This includes male and female labour force participation rates as well as unemployment  
36 rates.  
37  
38  
39  
40  
41  
42  
43  
44

45  
46 To analyse the gendered impact of tax policies, the main regressor is a binary variable. This  
47 represents the year of the introduction or increase in VAT, which must also coincide with IMF  
48 programs. For example, in 2023, Ghana secured an IMF bailout, and the VAT rate was effectively  
49 increased from 12.5% to 15%. In addition, a binary variable is used to denote periods when Ghana  
50 was under an IMF ECF program. This helps to assess the impact of being under an IMF program  
51 on gender outcomes. To strengthen the results and address concerns about endogeneity, the  
52  
53  
54  
55  
56  
57  
58  
59  
60

instrumental variable design is implemented. We use natural disaster as an instrument for IMF programs, with tax conditionality, following the argument by Kern et al. (2024) that natural disasters disrupt labour market outcomes, often necessitating IMF assistance. Thus, the frequency of natural disasters in a country would cause financial distress, necessitating an IMF bailout. The data on natural disasters is gleaned from the Centre for Research on the Epidemiology of Disasters (CRED). Similar to the IMF program, a binary variable is created to represent the occurrence of natural disasters, where at least 10 lives are lost or 100 people are affected.

Recognizing that IMF programs are typically implemented during crisis periods, we introduce control variables that may mitigate the crisis's impact to isolate the effects of tax policies on gender. Thus, this paper employs multiple control variables that may influence the relationship between the IMF program and gender outcomes. This includes Gross Domestic Product per capita (GDPpc), inflation (INF), financial crisis (FIN), and democracy (DEM). The logs of GDP per capita and inflation capture worsening economic situations, so that the effects of tax measures or the IMF ECF program will be fully reflected in the gendered outcomes. Inflation is measured by the Consumer Price Index (CPI). These data are also gleaned from the World Bank. Financial crisis is included as a binary variable using the updated version of the original data compiled by Laeven and Valencia (2018). In this regard, a financial crisis is noticed when there are significant signs of financial distress in the banking system (as indicated by significant bank runs, losses in the banking system, and/or bank liquidations) and when there are significant banking policy intervention measures in response to significant losses in the banking system. The first year these outcomes become systemic denotes the year of the financial crisis. It is included because a financial crisis fundamentally triggers IMF programs. Lastly, the polity index is used to measure democracy. Governments that prioritize democracy are more likely to promote the rights of women and are also more committed to international credibility. Accordingly, we interact IMF programs with democracy, following Detraz & Peksen (2016). This provides more insight into how IMF programs during periods of stable democracy influence labour market outcomes. It is expected that during periods of stable democracy, governments under an IMF program will prioritize the promotion of women's rights, thereby lessening the adverse impacts on their participation in the labour market.

## 5. Results and Discussion

1  
2  
3 The descriptive statistic in Table 2 shows the distributions of the variables used in the estimation.  
4  
5 The diagnostic statistics for the main estimates are presented alongside the results, as shown in  
6  
7 Table 4. Other relevant statistics, such as the residual and stability diagnostics, are presented in the  
8  
9 Appendix. This includes the tests for normality, serial correlation, autocorrelation,  
10  
11 heteroskedasticity, correct specification, and multicollinearity. The variables are normally  
12  
13 distributed, there is no serial correlation, no autocorrelation, no heteroskedasticity, and they are  
14  
15 correctly specified as presented in Appendix 1. The correlation matrix and variance inflation factor  
16  
17 in Appendices 2 and 3 show no concern for multicollinearity. Also, the cumulative sum of  
18  
19 recursive residuals (CUSUM) and the cumulative sum of squares of recursive residuals  
20  
21 (CUSUMQ) are displayed in Appendices 4 and 5. The CUSUM shows strong signs of parameter  
22  
23 stability over the period within the standard 5 percent critical bounds, while the CUSUMQ also  
24  
25 shows no structural breaks, but for a brief period between 2011 and 2013. After that, stability was  
26  
27 restored.

26 The primary estimates are presented in Tables 3 and 4. While Table 3 shows the long-run  
27  
28 estimate, the error correction model is shown in Table 4. First, the results suggest that a negative  
29  
30 relationship exists between being under an IMF program and the unemployment gap, although it  
31  
32 is not statistically significant. This is apparent in both the long- and short-run, as shown in the first  
33  
34 columns of Table 3 and Table 4. There is thus no discernible trend to show that under an IMF  
35  
36 program, women are disadvantaged compared to men in the labour market in terms of the  
37  
38 unemployment gap. However, the results indicate that the IMF-recommended tax reforms,  
39  
40 particularly those related to VAT imposition and subsequent upward adjustments, negatively  
41  
42 correlate with the unemployment gap. This result is statistically significant in both the short and  
43  
44 long run, as shown in the second columns of Tables 3 and 4.

43 To reiterate, a higher value of the unemployment gap indicates relatively less  
44  
45 unemployment among women. Hence, the negative correlation between IMF tax reforms and the  
46  
47 unemployment gap indicates that women are more adversely affected by unemployment than their  
48  
49 male counterparts when IMF-recommended tax reforms are implemented in Ghana. This is evident  
50  
51 from the coefficient of IMF with tax conditionality, which is negative and statistically significant  
52  
53 in both the long and short run. In the long run, the unemployment gap widens by 0.264% points  
54  
55 when the IMF imposes tax reforms. In the short run, it widens by 0.055% points. Thus, IMF  
56  
57 programs with tax conditionality exacerbate gender inequality in Ghana. This confirms the  
58  
59  
60

1  
2  
3 unemployment gap displayed in Figure 1.  
4

5 The intuition of this result is that VAT is a regressive tax, which widens the gender  
6 inequality gap. Besides, women tend to be more engaged in vulnerable employment than men.  
7 Hence, disturbances such as tax reforms that contract firms' productivity lead to layoffs, of which  
8 women are the most marginalized. Even for the self-employed, upward VAT adjustment is  
9 associated with higher compliance costs. This may eventually lead to business collapse and  
10 unemployment, particularly for small- and medium-sized enterprises where women are  
11 disproportionately represented. In this regard, Kern et al. (2024) and Blankton et al. (2019) argue  
12 that IMF programs have an adverse impact on women than on men, as the former are more likely  
13 to be engaged in less crisis-proof jobs. This finding aligns with those of Donno et al. (2024), who  
14 find that IMF programs with tax conditionality negatively correlate with women's labour force  
15 participation and positively correlate with women's unemployment. Thus, they argue that under  
16 the IMF program with tax conditionality, women exhibit lower labour force participation and  
17 higher unemployment. Our finding also aligns with Maisonnave and Chitiga (2021), who find that  
18 fiscal reforms increase the unemployment rates of women and lower their income levels in South  
19 Africa.  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

31 Besides the unemployment gap, different regressions are run with the labour force  
32 participation gap as the outcome variable. Although a negative coefficient is observed when the  
33 labour force participation gap is regressed on the IMF program, this relationship is not statistically  
34 significant in the long run to merit further discussion, as shown in the third column of Table 3.  
35 Thus, in the long run, no discernible effect is seen. However, in the short run, under an IMF  
36 program, the labour force participation of women is adversely affected as fewer women participate.  
37 Thus, the labour force participation gap widens by 0.001% points, to the detriment of women's  
38 economic empowerment. This is shown in column 3 in Table 4. The imposition and adjustment of  
39 VAT, although it shows a negative correlation with the labour force participation gap, is not  
40 statistically significant. This applies both in the long and short run. The study by Kern et al. (2024)  
41 confirms that IMF programs have a negative impact on the labour force participation gap, although  
42 this result is contingent upon the absence of control variables. When the relevant control variables  
43 are introduced, no consistent evidence is seen.  
44  
45  
46  
47  
48  
49  
50  
51  
52

53 The outcome mentioned above is confirmed using gender-disaggregated data in the error  
54 correction model displayed in Table 5. The IMF program is negatively correlated with the female  
55  
56  
57  
58  
59  
60

1  
2  
3 labour force participation rate and the male labour force participation rate in columns 3 - 4. This  
4 means that regardless of gender, IMF programs worsen the labour force participation rate.  
5 However, the adverse effect is more pronounced for women than for men, as their elasticity is  
6 higher. This is shown by the coefficients, which are -0.136 for females and -0.019 for males.  
7 Similarly, IMF programs aggravate the male unemployment rate in column 5, but no significant  
8 effect is observed for the female unemployment rate, which is not shown in the Tables to save  
9 space.  
10  
11  
12  
13  
14

15 To provide more insights, an interactive regression analysis is conducted. This result shows  
16 that although IMF programs have adverse effects on gendered outcomes, when IMF programs and  
17 IMF programs with tax conditionality are interacted with democracy, positive interactive effects  
18 are noticed in Table 5. First, in column 1, during IMF programs under governments with stable  
19 and good democratic practices, the labour force participation gap narrows, indicating more female  
20 labour force participation. Similarly, interacting IMF tax conditionality programs with democracy  
21 in column 2 narrows the labour force participation gap. Democratic regimes promote women's  
22 rights and help mitigate the adverse impacts of IMF programs on the labour force participation  
23 gap. Consistent with this result, Detraz and Peksen (2016) argue that democratic regimes have a  
24 higher respect for women's rights because democratically elected leaders are constrained by  
25 numerous institutional mechanisms, including the prospects of losing office through elections and  
26 systems of checks and balances.  
27  
28  
29  
30  
31  
32  
33  
34  
35

36 Endogeneity concerns are also addressed in this paper using the 2SLS instrumental  
37 variables approach. Instrumenting IMF tax conditionality programs with natural disasters yields  
38 relatively similar results, as shown in Table 6. First, the labour force participation gap widens  
39 during IMF programs with tax conditionality, suggesting less female participation in the labour  
40 force. Second, these programs have an adverse effect on both female and male labour force  
41 participation rates. However, the adverse effect is more pronounced for women than for men. This  
42 is due to higher elasticity. Nonetheless, no significant effect is noticed for the unemployment gap.  
43  
44  
45  
46  
47

48 In the primary model, with unemployment gap as the outcome variable, both GDP per  
49 capita and financial crisis are positively correlated with the unemployment gap. This means that  
50 an increase in per capita income has a positive effect on gender outcomes, thereby reducing gender  
51 inequality. Hence, there are no unemployment fears for women once the economy prospers. On  
52 the contrary, the financial crisis, which is a significant trigger for undergoing an IMF program  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 contrary to expectations, positively affects the unemployment gap. No significant relationship is  
4 observed between democracy, inflation, and the unemployment gap.  
5  
6  
7

## 8 **6. Conclusion, Recommendations, and Directions for Future Research**

9

10 Ghana, like most developing countries, turns to the IMF when it requires a financial bailout to  
11 stabilize its balance of payments operations. Due to Ghana's economic fragility, it has sought  
12 financial bailout from the IMF 17 times after independence. Nonetheless, the IMF bailout, which  
13 may restore macroeconomic stability, especially in the short term, is not without conditionality.  
14 One foremost conditionality is the imposition or upward adjustment of the VAT. However, the  
15 VAT is said to be regressive and gender sensitive. To adduce a shred of empirical econometric  
16 evidence, this paper investigates the relationship between being under an IMF program with tax  
17 conditionality and gender outcomes in Ghana. The ARDL and 2SLS instrumental variable  
18 estimation procedures are used.  
19  
20  
21  
22  
23  
24

25 The result shows that the unemployment gap between women and men widens during IMF  
26 programs, especially when tax conditionality is imposed. The evidence also suggests that, besides  
27 widening the labour force participation gap, the decline in labour force participation among women  
28 is more pronounced than that of men during IMF programs. Conversely, improved democratic  
29 regimes tend to mitigate the adverse impacts of IMF programs on the labour force participation  
30 gap through higher respect for women's rights.  
31  
32  
33  
34  
35

36 This study underscores the need for policymakers to incorporate gender concerns in public  
37 policy formulation. The periodic upward adjustments in the VAT rate should be reconsidered due  
38 to its adverse effects on women's economic participation, while not losing sight of revenue  
39 generation. Particularly, tax provisions that discriminate against secondary earners and adversely  
40 affect female labour force participation should be removed. The IMF should incorporate gender  
41 indicators in its performance metrics during program design. Additionally, disaggregated data on  
42 gender issues needs to be collected and analyzed appropriately. Finally, the government of Ghana  
43 should consolidate its democratic credentials by allowing more female participation in economic  
44 activities.  
45  
46  
47  
48  
49  
50

51 Future studies can consider incorporating a model that adequately reflects the realities of  
52 the informal labour market, where many women in Ghana are employed. These nuances could  
53 provide a vital context to enhance the overall gender analysis, offering a more comprehensive  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 understanding of the labour market's impact on women. Additionally, other significant fiscal  
4 policies, such as corporate tax changes or income tax reforms, which may affect labor market  
5 outcomes differently across genders, should also be considered.

**Table 1: Statistics of Gender Gap in Ghana, 2024**

| Indicator                                      | Female | Male  | Difference |
|--|--------|-------|------------|
| <b>Economic participation and opportunity</b>  |        |       |            |
| Labour force participation rate (%)            | 61.98  | 65.24 | -3.26      |
| Estimated earned income (\$ 1,000)             | 4.02   | 6.95  | -2.93      |
| Legislators, senior officials and managers (%) | 44.27  | 55.73 | -11.46     |
| Professional and technical workers (%)         | 41.67  | 58.33 | -16.66     |
| Unemployed adults (% of labour force)          | 3.51   | 2.87  | 0.64       |
| <b>Educational attainment</b>                  |        |       |            |
| Enrolment in primary education (%)             | 80.56  | 80.92 | -0.36      |
| Enrolment in secondary education (%)           | 76.61  | 76.96 | -0.35      |
| Enrolment in tertiary education (%)            | 19.77  | 21.00 | -1.23      |
| Graduates from tertiary education (%)          | 11.86  | 14.92 | -3.06      |

**Appendix 1: Residual and Stability Diagnostics**

| Test type                                  | Test statistics | P-value  | Interpretation of result                                    |
|--|-----------------|----------|---|
| Jarque-Bera Normality Test                 | 0.657625        | 0.719778 | Fail to reject the null hypothesis of normal distribution   |
| Correlogram of residuals (Q-statistics)    | 0.2382          | 0.626    | Fail to reject the null hypothesis of no autocorrelation    |
| Breusch-Godfrey Serial Correlation LM Test | 0.834488        | 0.4651   | Fail to reject the null hypothesis of no serial correlation |
| Ramsey RESET Test                          | 2.316522        | 0.1543   | Fail to reject the null hypothesis of correct specification |
| Heteroskedasticity Test: ARCH              | 1.343224        | 0.2584   | Fail to reject the null hypothesis of no heteroskedasticity |

**Appendix 2: Pairwise correlations**

| Variables            | (1)    | (2)    | (3)    | (4)    | (5)    | (6)   |
|----------------------|--------|--------|--------|--------|--------|-------|
| (1) IMF Program      | 1.000  |        |        |        |        |       |
| (2) Financial crisis | -0.175 | 1.000  |        |        |        |       |
| (3) Unemployment gap | 0.391  | -0.009 | 1.000  |        |        |       |
| (4) Democracy        | 0.058  | 0.043  | 0.469  | 1.000  |        |       |
| (5) Inflation        | 0.208  | 0.207  | -0.104 | -0.440 | 1.000  |       |
| (6) GDP per capita   | -0.316 | 0.096  | 0.163  | 0.662  | -0.422 | 1.000 |

**Appendix 3: Variance inflation factor**

|                  | VIF   | 1/VIF |
|------------------|-------|-------|
| GDP per capita   | 2.365 | .423  |
| Democracy        | 2.092 | .478  |
| Inflation        | 1.409 | .71   |
| IMF program      | 1.139 | .878  |
| Financial crisis | 1.107 | .903  |
| Mean VIF         | 1.623 | .     |
